20 **6.3.3.2 Integrated response options based on value chain management**

21 In this section, the impacts on desertification of integrated response options based on value chain
22 management are assessed.

23 **6.3.3.2.1 Integrated response options based on value chain management through demand 24 management**

25 Dietary change and waste reduction both result in decreased cropland and pasture extent (Bajželj et al.
26 2014a; Stehfest et al. 2009; Tilman and Clark 2014), reducing the pressure for desertification (Table
27 6.34).

1 Reduced post-harvest losses could spare 1.98 Mkm² of cropland globally (Kummu et al. 2012). Not
 2 all of this land could be subject to desertification pressure, so this represents that maximum area that
 3 could be relieved from desertification pressure by reduction of post-harvest losses. No studies were
 4 found linking material substitution to desertification.

5 Table 6.34 summarises the impacts on desertification of demand management options, with
 6 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
 7 (not exhaustive) references upon which the evidence is based.

Management of supply chains	No global estimates	No evidence	
Enhanced urban food systems	No global estimates	No evidence	
Improved food processing and retailing	No global estimates	No evidence	
Improved energy use in food systems	No global estimates	No evidence	

19

20 **6.3.3.3 Integrated response options based on risk management**

21 In this section, the impacts on desertification of integrated response options based on risk
 22 management are assessed.

23 There are regional case studies of urban sprawl contributing to desertification in Mediterranean
 24 climates in particular (Barbero-Sierra et al. 2013b; Stellmes et al. 2013), but no global figures.

25 Diversification may deliver some benefits for addressing desertification when it involves greater use
 26 of tree crops that may reduce the need for tillage (Antwi-Agyei et al. 2014). Many anti-
 27 desertification programmes call for diversification (Stringer et al. 2009), but there is little
 28 evidence on how many households had done so (Herrmann and Hutchinson 2005). There are no
 29 numbers for global impacts.

30 The literature is unclear on whether the use of local seeds has any relationship to desertification,
 31 although some local seeds are likely more adapted to arid climates and less likely to degrade land than

1 commercial introduced varieties (Mousseau 2015). Some anti-desertification programmes have also
2 shown more success using local seed varieties (Bassoum and Ghiggi 2010; Nunes et al. 2016).

3 Some disaster risk management approaches can have impacts on reducing desertification, like the
4 Global Drought Early Warning System (GDEWS) (currently in development), which will monitor
5 precipitation, soil moisture, evapotranspiration, river flows, groundwater, agricultural productivity
6 and natural ecosystem health. It may have some potential co-benefits to reduce desertification (Pozzi
7 et al. 2013). However, there are no figures yet for how much land area will be covered by such early
8 warning systems.

9 Risk sharing instruments, like pooling labour or credit, could help communities invest in anti-
10 desertification actions, but evidence is missing. Commercial crop insurance is likely to deliver no co-
11 benefits for prevention and reversal of desertification, as evidence suggests that subsidised insurance,
12 in particular, can increase crop production in marginal lands. Crop insurance could have been
13 responsible for shifting up to 0.9% of rangelands to cropland in the Upper US Midwest (Claassen et
14 al. 2011).

15 Table 6.36 summarises the impact on desertification for options based on risk management, with
16 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
17 (not exhaustive) references upon which the evidence is based.

18 **Table 6.36 Effects on desertification of response options based on risk management**

Integrated response option	Potential	Confidence	Citation
Management of urban sprawl	>5 thousand km ²	Low confidence	Barbero-Sierra et al. 2013b
Livelihood diversification	No global estimates	Low confidence	Herrmann and Hutchinson 2005
Use of local seeds	No global estimates	No evidence	
Disaster risk management	No global estimates	No evidence	Pozzi et al. 2013a
Risk sharing instruments	Likely negative impacts but not quantified	Low confidence	Claassen et al. 2011

19 **6.3.4 Potential of the integrated response options for addressing land degradation**

20 In this section, the impacts of integrated response options on land degradation are assessed.

21 **6.3.4.1 Integrated response options based on land management**

22 In this section, the impacts on land degradation of integrated response options based on land
23 management are assessed.

24 **6.3.4.1.1 Integrated response options based on land management in agriculture**

25 Burney et al. (2010) estimated that an additional global cropland area of 11.11–15.14 Mkm² would
26 have been needed if productivity had not increased between 1961 and 2000. As for desertification,
27 given that agricultural expansion is a main driver of land degradation (FAO and ITPS 2015),
28 increased food productivity has prevented up to 11.11–15.14 Mkm² from exploitation and land
29 degradation (Table 6.37).
30

31 Land degradation can be addressed by the implementation of improved cropland, livestock and
32 grazing land management practices, such as those outlined in the recently published Voluntary
33 Guidelines for Sustainable Soil Management (FAO 2017b). Each one could potentially affect
34 extensive surfaces, not less than 10 Mkm². The Guidelines include a list of practices aiming at
35 minimising soil erosion, enhancing soil organic matter content, fostering soil nutrient balance and
36 cycles, preventing, minimising and mitigating soil salinisation and alkalinisation, soil contamination,
37 soil acidification, and soil sealing, soil compaction, and improving soil water management. Land

1 cover and land cover change are key factors and indicators of land degradation. In many drylands,
2 land cover is threatened by overgrazing, so management of stocking rate and grazing can help to
3 prevent the advance of land degradation Smith et al. (2016c).

4 Agroforestry can help stabilise soils to prevent land degradation, so given that there are is around 10
5 Mkm² of land with more than 10% tree cover (Garrity, 2012), agroforestry could benefit up to 10
6 Mkm² of land.

7 Agricultural diversification usually aims at increasing climate and food security resilience, such as
8 under “climate smart agriculture” approaches (Lipper et al. 2014). Both objectives are closely related
9 to land degradation prevention, potentially affecting 1–5 Mkm².

10 Shifting from grassland to tilled crops increases erosion and soil loss, so there are significant benefits
11 for addressing land degradation, by stabilising degraded soils (Chapter 3). Since cropland expansion
12 during 1985 to 2005 was 17.4 thousand km² yr⁻¹ (Foley et al.,2009), and not all of this expansion will
13 be from grasslands or degraded land, the maximum contribution of prevention of conversion of
14 grasslands to croplands is 17.4 thousand km² yr⁻¹, a small global benefit for control of land
15 degradation (Tale 6.37).

16 Most land degradation processes that are sensitive to climate change pressures (e.g. erosion, decline in
17 soil organic matter, salinisation, waterlogging, drying of wet ecosystems) can benefit from integrated
18 water management. Integrated water management options include management to reduce aquifer and
19 surface water depletion, and to prevent over extraction, and provide direct co-benefits for prevention
20 of land degradation. Land management practices implemented for climate change mitigation may also
21 affect water resources. Globally, water erosion is estimated to result in the loss of 23–42 MtN and
22 14.6–26.4 MtP annually (Pierzynski et al., 2017). Forests influence the storage and flow of water in
23 watersheds (Eisenbies et al. 2007) and are therefore important for regulating how climate change will
24 impact landscapes.

25 Table 6.37 summarises the impact on land degradation of options in agriculture, with confidence
26 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
27 exhaustive) references upon which the evidence in based.

28 **Table 6.37 Effects on land degradation of response options in agriculture**

Agroforestry	10 Mkm ² (with >10% tree cover)	Medium confidence	Garrity 2012
Agricultural diversification	1-5 Mkm ²	Medium confidence	Lambin and Meyfroidt 2011
Reduced grassland conversion to cropland	Up to 17.4 thousand km ² yr ⁻¹	Low confidence	Foley et al. 2011
Integrated water management	0.01 Mkm ²	Medium confidence	Pierzynski et al., 2017; UNCCD, 2011

29 **6.3.4.1.2 Integrated response options based on land management in forestry**

30 Based on the extent of forest exposed to degradation (Gibbs and Salmon 2015), the estimated global
31 potential effect for reducing land degradation, e.g. through reduced soil erosion (Borrelli et al. 2017),
32 is large for both improved forest management and for reduced deforestation and forest degradation
33

1 when cumulated for at least 20 years (Table 6.38) The uncertainty of these global estimates is high.
 2 More robust qualitative and some quantitative estimates are available at regional level. For example,
 3 in Indonesia, Santika et al. (2017) demonstrated that reduced deforestation (Sumatra and Kalimantan
 4 islands) contributed to reduce significantly land degradation.

5 Forest restoration is a key option to achieve the overarching frameworks to reduce land degradation at
 6 global scale, such as for example, Zero Net Land Degradation (ZNLD; UNCCD 2012) and Land
 7 Degradation Neutrality (LDN), not only in drylands (Safriel 2017). Indeed, it has been estimated that
 8 more than 20 Mkm² are suitable for forest and landscape restoration, of which 15 Mkm² may be
 9 devoted to mosaic restoration (UNCCD 2012). Moreover, the Bonn Challenge aims to restore 1.5
 10 Mkm² of deforested and degraded land by 2020, and 3.5 Mkm² by 2030
 11 (<http://www.bonnchallenge.org/content/challenge>). Under a restoration and protection scenario
 12 (implementing restoration targets), Wolff et al. (2018) simulated that there will be a global increase in
 13 net tree cover of about 4 Mkm² by 2050 (Table 6.38). At local level, Brazil's Atlantic Restoration
 14 Pact aims to restore 0.15 Mkm² of forest areas in 40 years (Melo et al. 2013). The Y Ikatu Xingu
 15 campaign (launched in 2004) aims to contain deforestation and degradation processes by reversing the
 16 liability of 3 thousand km² in the Xingu Basin, Brazil (Durigan et al. 2013).

17 Afforestation and reforestation are land management options frequently used to address land
 18 degradation (see Section 6.3.3.1.2 for details; Table 6.38).

19 Table 6.38 summarises the impact on land degradation of options in forestry, with confidence
 20 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
 21 exhaustive) references upon which the evidence is based.

Reduced deforestation and degradation	> 3 Mkm ² (effects cumulated for at least 20 years)	Low confidence	Gibbs and Salmon 2015; Keenan et al. 2015
Reforestation and forest restoration	20 Mkm ² suitable for restoration > 3 Mkm ² by 2050 (net increase in tree cover for forest restoration)	Medium confidence	UNCCD 2012; Wolff et al. 2018
Afforestation	2-25.8 Mkm ² by the end of the century	Low confidence	Griscom et al. 2017a; Kreidenweis et al. 2016a; Popp et al. 2017

23

24 **6.3.4.1.3 Integrated response options based on land management of soils**

25 Increasing soil organic matter content is a measure to address land degradation. With around 120
 26 thousand km² lost to degradation every year, and over 3.2 billion people negatively impacted by land
 27 degradation globally (IPBES 2018), practices designed to increase soil organic carbon have a large
 28 potential to address land degradation, estimated to affect over 11 Mkm² globally (Lal, 2004; Table
 29 6.39).

30 Control of soil erosion could have large benefits for addressing land degradation. Soil erosion control
 31 could benefit up to 1.50 Mkm² of land to 2050 (IPBES 2018). Lal (2004) suggested interventions to
 32 prevent wind and water erosion (two of the four main interventions proposed to address land
 33 degradation), could restore 11 Mkm² of degraded and desertified soils globally (Table 6.39).

34 Oldeman et al. (1991) estimated the global extent soil affected by salinisation is 0.77 Mkm² yr⁻¹,
 35 which sets the upper limit on the area that could benefit from measures to address soil salinisation

1 (Table 6.39). The global extent of chemical soil degradation (salinisation, pollution, and acidification)
 2 is about 1.03 Mkm² (Oldeman et al. 1991) giving the maximum extent of land that could benefit from
 3 the management of pollution and acidification.

4 Biochar could provide moderate benefits for the prevention or reversal of land degradation, by
 5 improving water holding capacity, improving nutrient use efficiency, managing heavy metal pollution
 6 and other co-benefits (Sohi 2012), though the global effects are not quantified.

7 Table 6.39 summarises the impact on land degradation of soil-based options, with confidence
 8 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
 9 exhaustive) references upon which the evidence is based.

10

Reduced soil erosion	11 Mkm ²	Medium confidence	Lal 2004
Reduced soil salinisation	0.77 Mkm ² yr ⁻¹	Medium confidence	Qadir et al. 2013a; FAO 2016;
Reduced soil compaction	10 Mkm ²	Low confidence	FAO and ITPS 2015; Hamza and Anderson 2005a
Biochar addition to soil	Positive but not quantified globally	Low confidence	Chapter 4

11

12 **6.3.4.1.4 Integrated response options based on land management across all/other ecosystems**

13 For fire management, details of estimates of the impact of wildfires (and thereby the potential impact
 14 of their suppression) are given in Section 6.3.3.1.4 (Table 6.40).

15 Management of landslides and natural hazards aims at controlling a severe land degradation process
 16 affecting sloped and hilly areas, many of them with poor rural inhabitants (FAO et al. 2015; Gariano
 17 and Guzzetti 2016b), but the global potential has not been quantified.

18 There are no global data on the impacts of management of invasive species / encroachment on land
 19 degradation, though the impact is presumed to be positive.

20 Since large areas of coastal wetlands are degraded, restoration could potentially deliver moderate
 21 benefits for addressing land degradation, with 0.29 Mkm² globally considered feasible for restoration
 22 (Griscom et al. 2017a; Table 6.40).

23 Considering that large areas (0.46 Mkm²) of global peatlands are degraded and considered suitable for
 24 restoration (Griscom et al. 2017), peatland restoration could deliver moderate benefits for addressing
 25 land degradation (Table 6.40).

26 There are no global estimates of the effects of biodiversity conservation on reducing degraded lands.
 27 However, at local scale, biodiversity conservation programmes have been demonstrated to stimulate
 28 gain of forest cover over large areas over the last three decades (e.g. in China; Zhang et al. 2013).
 29 Management of wild animals can influence land degradation processes by grazing, trampling and
 30 compacting soil surfaces, thereby altering surface temperatures and chemical reactions affecting
 31 sediment and carbon retention (Cromsigt et al. 2018).

32 Table 6.40 summarises the impact on land degradation of options in all/other ecosystems, with
 33 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
 34 (not exhaustive) references upon which the evidence is based.

35

Table 6.40 Effects on land degradation of response options in all/other ecosystems

Integrated response option	Potential	Confidence	Citation

Restoration and reduced conversion of peatlands	0.46 Mkm ²	Medium confidence	Griscom et al. 2017a
Biodiversity conservation	No global estimates	No evidence	

1

2 **6.3.4.1.5 Integrated response options based on land management specifically for CDR**

3 While spreading of crushed minerals onto land as part of enhanced weathering can provide soil / plant
4 nutrients in nutrient-depleted soils, can increase soil organic carbon stocks and can help to replenish
5 eroded soil (Beerling et al. 2018), there is no literature on the global potential for addressing land
6 degradation.

7 Large-scale production of bioenergy can require significant amounts of land (Smith et al. 2016c;
8 Clarke and Jiang 2014b; Popp et al. 2017), much as 15 Mkm² in 2°C scenarios (Popp et al. 2017),
9 increasing pressures for land conversion and land degradation (Table 6.13). However, bioenergy
10 production can either increase (Robertson et al. 2017c; Mello et al. 2014a) or decrease (FAO 2011;
11 Lal 2014) soil organic matter, depending on where it is produced and how it is managed. These effects
12 are not included in the quantification in Table 6.41.

13 Table 6.41 summarises the impact on land degradation of options specifically for CDR, with
14 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
15 (not exhaustive) references upon which the evidence is based.

16 **Table 6.41 Effects on land degradation of response options specifically for CDR**

Integrated response option	Potential	Confidence	Citation
Enhanced weathering of minerals	Positive but not quantified	Low confidence	Beerling et al. 2018

17

18 **6.3.4.2 Integrated response options based on value chain management**

19 In this section, the impacts on land degradation of integrated response options based on value change
20 management are assessed.

21 **6.3.4.2.1 Integrated response options based on value chain management through demand management**

22
23 Dietary change and waste reduction both result in decreased cropland and pasture extent (Bajželj et al.
24 2014; Stehfest et al. 2009; Tilman and Clark 2014a), reducing the pressure for land degradation
25 (Table 6.15). Reduced post-harvest losses could spare 1.98 Mkm² of cropland globally (Kummu et al.
26 2012) meaning that land degradation pressure could be relieved from this land area through reduction
27 of post-harvest losses. The effects of material substitution on land degradation depend on
28 management practice; some forms of logging can lead to increased land degradation (Chapter 4).

1 Table 6.42 summarises the impact on land degradation of demand management options, with
 2 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
 3 (not exhaustive) references upon which the evidence is based.

4 **Table 6.42 Effects on land degradation of response options based on demand management**

Integrated response option	Potential	Confidence	Citation

Reduced post-harvest losses	1.98 Mkm ²	Medium confidence	Kummu et al. 2012a
Reduced food waste (consumer or retailer)	7 Mkm ²	Medium confidence	Bajželj et al. 2014
Material substitution	No global estimates	No evidence	

5

6 **6.3.4.2.2 Integrated response options based on value chain management through supply** 7 **management**

8 There are no global estimates of the impact on land degradation of enhanced urban food systems,
 9 improved food processing, retailing, or improved energy use in food systems.

10 There is evidence that sustainable sourcing could reduce land degradation, as the explicit goal of
 11 sustainable certification programs is often to reduce deforestation or other unsustainable land uses.
 12 Over 4 Mkm² of forests are certified for sustainable harvesting (PEFC/FSC 2018), although it is not
 13 clear if all these lands would be at risk of degradation without certification. While the food price
 14 instability of 2007/2008 increased financial investment in crop expansion (especially through so-
 15 called land grabbing), and thus better management of supply chains might have reduced this amount,
 16 no quantification of the total amount of land acquired, nor the possible impact of this crop expansion
 17 on degradation, has been recorded (McMichael and Schneider 2011a; McMichael 2012).

18 Table 6.43 summarises the impact on land degradation of supply management options, with
 19 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
 20 (not exhaustive) references upon which the evidence is based.

21 **Table 6.43 Effects on land degradation of response options based on supply management**

Management of supply chains	No global estimates	No evidence	
Enhanced urban food systems	No global estimates	No evidence	
Improved food processing and retailing	No global estimates	No evidence	
Improved energy use in food systems	No global estimates	No evidence	

22

23 **6.3.4.3 Integrated response options based on risk management**

24 In this section, the impacts on land degradation of integrated response options based on risk
 25 management are assessed.

26 Urban expansion has been identified as a major culprit in soil degradation in some countries; for
 27 example, urban expansion in China has now affected 0.2 Mkm², or almost one-sixth of the cultivated
 28 land total, causing an annual grain yield loss of up to 10 Mt, or around 5-6% of cropland production.
 29 Cropland production losses of 8-10% by 2030 are expected under model scenarios of urban expansion
 30 (Bren d'Amour et al. 2016). Pollution from urban development has included water and soil pollution
 31 from industry and wastes and sewage as well as acid deposition from increasing energy use in cities
 32 (Chen 2007a), all resulting in major losses to Nature's Contributions to People from urban conversion
 33 (Song and Deng 2015). Soil sealing from urban expansion is a major loss of soil productivity across

1 many areas. The World Bank has estimated that new city dwellers in developing countries will require
2 160–500 m² per capita, converted from non-urban to urban land (Barbero-Sierra et al. 2013a; Angel et
3 al 2005).

4 Degradation can be a driver leading to livelihood diversification (Batterbury 2001; Lestrelin and
5 Giordano 2007). Diversification has the potential to deliver some reversal of land degradation, if
6 diversification involves adding non-traditional crops or trees that may reduce the need for tillage
7 (Antwi-Agyei et al. 2014). China's Sloping Land conversion programme has had livelihood
8 diversification benefits and is said to have prevented degradation of 93 thousand km² of land (Liu
9 et al. 2015). However, Warren (2002) provides conflicting evidence that more diverse-income
10 households had increased degradation on their lands in Niger, and Palacios et al. (2013) associate
11 landscape fragmentation with increased livelihood diversification in Mexico.

12 Use of local seeds may play a role in addressing land degradation due to the likelihood of local seeds
13 being less dependent on inputs such as chemical fertilisers or mechanical tillage; for example, in
14 India, local legumes are retained in seed networks while commercial crops like sorghum and rice
15 dominate food markets (Reisman 2017a). However, there are no global figures.

16 Disaster Risk Management systems can have some positive impacts on prevention and reversal of
17 land degradation, like the Global Drought Early Warning System (see section 6.3.3.3) (Pozzi et al.
18 2013).

19 Risk sharing instruments could have benefits for reduced degradation, but there are no global
20 estimates. Commercial crop insurance is likely to deliver no co-benefits for prevention and reversal of
21 degradation. One study found a 1% increase in farm receipts generated from subsidised farm
22 programmes (including crop insurance and others) increased soil erosion by 0.3 t ha⁻¹ (Goodwin and
23 Smith 2003). Wright and Wimberly (2013) found a 5310 km² decline in grasslands in the Upper
24 Midwest of the US during 2006-2010 due to crop conversion driven by higher prices and access to
25 insurance.

26 Table 6.44 summarises the impact on land degradation of risk management options, with confidence
27 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
28 exhaustive) references upon which the evidence is based.

29 **Table 6.44 Effects on land degradation of response options based on risk management**

Integrated response option	Potential	Confidence	Citation
Management of urban sprawl	>0.2 Mkm ²	Medium confidence	Chen 2007b; Zhang 2000
Livelihood diversification	>0.1 Mkm ²	Low confidence	Liu and Lan 2015
Use of local seeds	No global estimates	No evidence	
Disaster risk management	No global estimates	No evidence	Pozzi et al. 2013

31 **6.3.5 Potential of the integrated response options for addressing food security**

32 In this section, the impacts of integrated response options on food security are assessed.

33 **6.3.5.1 Integrated response options based on land management**

34 In this section, the impacts on food security of integrated response options based on land management
35 are assessed.

1 **6.3.5.1.1 *Integrated response options based on land management in agriculture***

2 Increased food productivity has fed many millions of people, who could not have otherwise been fed.
3 Erisman et al. (2008) estimated that over 3 billion people worldwide could not have been fed without
4 increased food productivity arising from N fertilisation (Table 6.45).

5 Improved cropland management to achieve food security aims at closing yield gaps by increasing use
6 efficiency of essential inputs such as water and nutrients. Large production increases (45–70% for
7 most crops) are possible from closing yield gaps to 100% of attainable yield, by increasing fertiliser
8 use and irrigation, but overuse of nutrients could cause adverse environmental impacts (Mueller et al.
9 2012). This improvement can impact 1000 million people.

10 Improved grazing land management includes grasslands, rangelands and shrublands, and all sites on
11 which pastoralism is practiced. In general terms, continuous grazing may cause severe damage to
12 topsoil quality, through e.g. compaction. This damage may be reversed by short grazing exclusion
13 periods under rotational grazing systems (Greenwood and McKenzie 2001; Drewry 2006; Taboada et
14 al. 2011). Due to the widespread diffusion of pastoralism, improved grassland management may
15 potentially affect more than 1000 million people, many of them under subsistence agricultural
16 systems.

17 Meat, milk, eggs, and other animal products, including fish and other seafoods, will play an important
18 role in achieving food security (Reynolds et al. 2015). Improved livestock management with different
19 animal types and feeds may also impact one million people (Herrero et al. 2016). Ruminants are
20 efficient converters of grass into human edible energy and protein and grassland-based food
21 production can produce food with a comparable carbon footprint to mixed systems (O'Mara 2012b).
22 However, in the future, livestock production will increasingly be affected by competition for natural
23 resources, particularly land and water, competition between food and feed and by the need to operate
24 in a carbon-constrained economy (Thornton et al. 2009a).

25 Currently, over 1.3 billion people are on degrading agricultural land, and the combined impacts of
26 climate change and land degradation could reduce global food production by 10% by 2050. Since
27 agroforestry could help to address land degradation, up to 1.3 billion people could benefit in terms of
28 food security through agroforestry.

29 Agricultural diversification is not always economically viable; technological, biophysical,
30 educational, and cultural barriers may emerge that limit the adoption of more diverse farming systems
31 by farmers (Section 6.4.1). Nevertheless, diversification could benefit 1000 million people, many of
32 them under subsistence agricultural systems (Birthal et al. 2015; Massawe et al. 2016; Waha et al.
33 2018).

34 Cropland expansion during 1985 to 2005 was 17 thousand km² yr⁻¹ (Foley et al. 2005). Given that
35 cropland productivity (global average of 250 kg protein ha⁻¹ yr⁻¹ for wheat; (Clark and Tilman 2017)
36 is greater than that of grassland (global average of about 10 kg protein ha⁻¹ yr⁻¹ for beef/mutton; (Clark
37 and Tilman 2017), prevention of this conversion to cropland would have led to a loss of about 0.4 Mt
38 protein yr⁻¹ globally. Given an average protein consumption in developing countries of 25.5 kg protein
39 yr⁻¹ (equivalent to 70g person⁻¹ day⁻¹; FAO, 2018), this is equivalent to the protein consumption of
40 16.4 million people each year (Table 6.45).

41 Integrated water management provides direct benefits to food security by improving agricultural
42 productivity (Chapter 5; Tilman et al. 2011; Godfray and Garnett 2014), thereby potentially impacting
43 the livelihood and well-being of >1000 million people (Campbell et al. 2016) affected by hunger and
44 highly impacted by climate change. Increasing water availability and reliable supply of water for
45 agricultural production using different techniques of water harvesting, storage, and its judicious
46 utilisation through farm ponds, dams, and community tanks in rainfed agriculture areas have been
47 presented by Rao (2017) and Rivera-Ferre et al. (2016).

1 Table 6.45 summarises the impact on food security of options in agriculture, with confidence
 2 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
 3 exhaustive) references upon which the evidence is based.

4 **Table 6.45 Effects on food security of response options in agriculture**

Integrated response option	Potential	Confidence	Citation
Increased food productivity	3000 million people	High confidence	Erisman et al. 2008
Improved cropland management	>1000 million people	Low confidence	Campbell et al. 2014; Lipper et al. 2014
Improved grazing land management	>1000 million people	Low confidence	Herrero et al. 2016
Improved livestock management	>1000 million people	Low confidence	Herrero et al. 2016
Agroforestry	Up to 1300 million people	Low confidence	Sasha et al. 2018
Agricultural diversification	>1000 million people	Low confidence	Birthal et al. 2015; Massawe et al. 2016; Waha et al. 2018
Reduced grassland conversion to cropland	Negative impact on 16.4 million people	Low confidence	Clark and Tilman 2017; FAO, 2018
Integrated water management	>1000 million people	High confidence	Campbell et al. 2016

5

6 **6.3.5.1.2 Integrated response options based on land management in forestry**

7 Forests play a major role in providing food to local communities (non-timber forest products,
 8 mushrooms, fodder, fruits, berries etc.), and diversify daily diets directly or indirectly through
 9 improving productivity, hunting, diversifying tree-cropland-livestock systems, and grazing in forests.
 10 Based on the extent of forest contributing to food supply, considering the people undernourished
 11 (Rowland et al. 2017; FAO, IFAD, and WFP, 2013), and the annual deforestation rate (Keenan et al.
 12 2015), the global potential to enhance food security is moderate for improved forest management and
 13 small for reduced deforestation (Table 6.46). The uncertainty of these global estimates is high. More
 14 robust qualitative and some quantitative estimates are available at regional level. For example,
 15 managed natural forests, shifting cultivation and agroforestry systems are demonstrated to be crucial
 16 to food security and nutrition for hundreds of million people in rural landscapes worldwide
 17 (Sunderland et al. 2013; Vira et al. 2015). According to Erb et al. (2016), deforestation would not be
 18 needed to feed the global population by 2050, in terms of quantity and quality of food. At local level,
 19 Cerri et al. (2018) suggested that reduced deforestation, along with integrated cropland-livestock
 20 management, would positively impact more than 120 million people in the Cerrado, Brazil. In Sub-
 21 Saharan Africa, where population and food demand are projected to continue to rise substantially,
 22 reduced deforestation may have strong positive effects on food security (Doelman et al. 2018).

23 Afforestation and reforestation negatively impact food security (Boysen et al. 2017b; Frank et al.
 24 2017; Kreidenweis et al. 2016b). It is estimated that large-scale afforestation plans could cause
 25 increases in food prices of 80% by 2050 (Kreidenweis et al. 2016b), and more general mitigation
 26 measures in the AFOLU sector can translate into a rise in undernourishment of 80–300 million people
 27 (Frank et al. 2017) (Table 6.16). For reforestation, the potential adverse side-effects with food security
 28 are smaller than afforestation, because forest regrows on recently deforested areas, and its impact
 29 would be felt mainly through impeding possible expansion of agricultural areas. On a smaller scale,
 30 forested land also offers benefits in terms of food supply, especially when forest is established on
 31 degraded land, mangroves, and other land that cannot be used for agriculture. For example, food from
 32 forests represents a safety-net during times of food and income insecurity (Wunder et al., 2014), and

1 wild harvested meat and freshwater fish provides 30-80% of protein intake from many rural
2 communities (McIntyre et al., 2016; Nasi et al., 2011).

3 Table 6.46 summarises the impact on food security of options in forestry, with confidence estimates
4 based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not exhaustive)
5 references upon which the evidence is based.

6 **Table 6.46 Effects on food security of response options in forestry**

Integrated response option	Potential	Confidence	Citation
Improved forest management	Positive impact on < 100 million people	Low confidence	FAO, IFAD & WFP, 2013; Rowland et al. 2017
Reduced deforestation and degradation	Positive impact on < 1 million people	Low confidence	FAO, IFAD & WFP, 2013; Keenan et al. 2015; Rowland et al. 2017
Reforestation and forest restoration	See afforestation		
Afforestation	Negative impact on > 100 million people	Medium confidence	Boysen et al. 2017b; Frank et al. 2017; Kreidenweis et al. 2016b

7

8 **6.3.5.1.3 Integrated response options based on land management of soils**

9 Increasing soil organic matter stocks can increase yield and improve yield stability (Lal 2006b; Pan et
10 al. 2009; Soussana et al. 2019), though this is not universally seen (Hijbeek et al., 2017). Lal (2006b)
11 concludes that crop yields can be increased by 20–70 kg ha⁻¹, 10–50 kg ha⁻¹ and 30–300 kg ha⁻¹ for
12 maize for wheat, rice and maize, respectively, for every 1 t C ha⁻¹ increase in soil organic carbon in
13 the root zone. Increasing soil organic carbon by 1 t C ha⁻¹ could increase food grain production in
14 developing countries by 32 Mt yr⁻¹ (Lal 2006b). Frank et al. (2017) estimate that soil carbon
15 sequestration could reduce calorie loss associated with agricultural mitigation measures by 65%,
16 saving 60–225 million people from undernourishment compared to a baseline without soil carbon
17 sequestration (Table 6.47).

18 Lal (1998) estimated the risks of global annual loss of food production due to accelerated erosion to
19 be as high as 190 Mt yr⁻¹ of cereals, 6 Mt yr⁻¹ of soybean, 3 Mt yr⁻¹ of pulses and 73 Mt yr⁻¹ of roots
20 and tubers. Considering only cereals, if we assume per-capita annual grain consumption in developing
21 countries to be 300 kg yr⁻¹ (estimated based on data included in Pradhan et al., 2013; FAO, 2018;
22 FAO et al., 2018; and World Bank 2018a), the loss of 190 Mt yr⁻¹ of cereals is equivalent to that
23 consumed by 633 million people, annually (Table 6.47).

24 Though there are biophysical barriers, such as access to appropriate water sources and limited
25 productivity of salt-tolerant crops, prevention / reversal of soil salinisation could benefit 1–100
26 million people (Qadir et al. 2013a). Soil compaction affects crop yields, so prevention of compaction
27 could benefit an estimated 1–100 million people globally (Anderson and Peters 2016).

28 Biochar on balance, could provide moderate benefits for food security by improving yields by 25% in
29 the tropics, but with more limited impacts in temperate regions (Jeffery et al. 2017), or through
30 improved water holding capacity and nutrient use efficiency (Chapter 5; Sohi 2012). These benefits
31 could, however, be tempered by additional pressure on land if large quantities of biomass are required
32 as feedstock for biochar production, thereby causing potential conflicts with food security (Smith
33 2016b). Smith (2016b) estimated that 0.4–2.6 Mkm² of land would be required for biomass feedstock
34 to deliver 2.57 GtCO₂e yr⁻¹ of CO₂ removal. If biomass production occupied 2.6 Mkm² of cropland,
35 equivalent to around 20% of the global cropland area, this could potentially have a large effect on
36 food security, although Woolf et al. (2010) argue that abandoned cropland could be used to supply
37 biomass for biochar, thus avoiding competition with food production. Similarly, Woods et al (2015)
38 estimate that 5-9 Mkm² of land is available for biomass production without compromising food

1 security and biodiversity, considering marginal and degraded land and land released by pasture
2 intensification (Table 6.47).

3 Table 6.47 summarises the impact on food security of soil-based options, with confidence estimates
4 based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not exhaustive)
5 references upon which the evidence is based.

6 **Table 6.47 Effects on food security of soil-based response options**

Integrated response option	Potential	Confidence	Citation
Increased soil organic carbon content	60-225 million people	Low confidence	Frank et al. 2017
Reduced soil erosion	633 million people yr ⁻¹	Low confidence	FAO, 2018; FAO et al. 2018; Lal 1998; Pradhan et al. 2013; World Bank 2018a
Reduced soil salinisation	1-100 million people	Low confidence	Qadir et al. 2013a
Reduced soil compaction	1-100 million people	Low confidence	Anderson and Peters 2016
Biochar addition to soil	Range from positive impact in the tropics from biochar addition to soil to a maximum potential negative impact on >100 million people by worst-case conversion of 20% of global cropland	Low confidence	Jeffery et al. 2017; worse case negative impacts calculated from area values in Smith 2016b

7

8 **6.3.5.1.4 Integrated response options based on land management across all/other ecosystems**

9 FAO (2015) calculated that damage from forest fires between 2003 and 2013 impacted a total of 49
10 thousand km² of crops with the vast majority in Latin America. Based on the world cereal yield in
11 2013 reported by Word Bank (2018b) (3.8 t ha⁻¹), the loss of 49 thousand km² of crops is equivalent to
12 18.6 Mt yr⁻¹ of cereals lost. Assuming annual grain consumption per capita to be 300 kg yr⁻¹
13 (estimated based on data included in Pradhan et al., 2013; FAO, 2018; FAO et al., 2018; and World
14 Bank 2018a), the loss of 18.6 Mt yr⁻¹ would remove cereal crops equivalent to that consumed by 62
15 million people (Table 6.48).

16 Landslides and other natural hazards affect 1–100 Million people globally, so preventing them could
17 provide food security benefits to this many people.

18 In terms of measures to tackle pollution, including acidification, Shindell et al. (2012) considered
19 about 400 emission control measures to reduce ozone and black carbon (BC). This strategy increases
20 annual crop yields by 30–135 Mt due to ozone reductions in 2030 and beyond. If annual grain
21 consumption per capita is assumed as 300 kg yr⁻¹ (estimated based on data included in Pradhan et al.,
22 2013; FAO, 2018; FAO et al., 2018; and World Bank 2018a), increase in annual crop yields by 30–
23 135 Mt feeds 100–450 million people.

24 There are no global data on the impacts of management of invasive species / encroachment on food
25 security.

26 Since large areas of converted coastal wetlands are used for food production (e.g., mangroves
27 converted for aquaculture; (Naylor et al. 2000b), restoration of coastal wetlands could displace food
28 production and damage local food supply, potentially leading to adverse impacts on food security,
29 though these effects are likely to be very small given that only 0.3% of human food comes from the

1 oceans and other aquatic ecosystems (Pimentel 2006), and that the impacts could be offset by careful
2 management, such as the careful siting of ponds within mangroves (Naylor et al. 2000b) (Table 6.46).

3 Around 14-20% (0.56–0.80 Mkm²) of the global 4 Mkm² of peatlands are used for agriculture, mostly
4 for meadows and pasture, meaning that if all of these peatlands were removed from production, 0.56–
5 0.80 Mkm² of agricultural land would be lost. Assuming livestock production on this land (since it is
6 mostly meadow and pasture) with a mean productivity of 9.8 kg protein ha⁻¹ yr⁻¹ (calculated from land
7 footprint of beef/mutton in (Clark and Tilman 2017)), and average protein consumption in developing
8 countries of 25.5 kg protein yr⁻¹ (equivalent to 70g person⁻¹ day⁻¹; FAO, 2018), this would be
9 equivalent to 21–31 million people no longer fed from this land (Table 6.46).

10 There are no global estimates on how biodiversity conservation improves nutrition (i.e. number of
11 nourished people). Biodiversity, and its management, is crucial for improving sustainable and
12 diversified diets (Global Panel on Agriculture and Food Systems for Nutrition 2016). Indirectly, the
13 loss of pollinators (due to combined causes, including the loss of habitats and flowering species)
14 would contribute to 1.42 million additional deaths per year from non-communicable and malnutrition-
15 related diseases, and 27.0 million lost disability-adjusted life-years (DALYs) per year (Smith et al.
16 2015). However, at the same time, some options to preserve biodiversity, like protected areas, may
17 potentially conflict with food production by local communities (Molotoks et al. 2017).

18 Table 6.48 summarises the impact on food security of response options in all/other ecosystems, with
19 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
20 (not exhaustive) references upon which the evidence is based.

21 **Table 6.48 Effects on food security of response options in all/other ecosystems**

Integrated response option	Potential	Confidence	Citation
Fire management	~62 million people	Low confidence	FAO 2015; FAO 2018; FAO et al. 2018; Pradhan et al. 2013; World Bank 2018a,b
Reduced landslides and natural hazards	1-100 million people	Low confidence	Campbell 2015
Reduced pollution including acidification	Increase annual crop yields 30-135 Mt globally; feeds 100-450 million people	Low confidence	Shindell et al. 2012; FAO, 2018; FAO et al., 2018; Pradhan et al. 2013; World Bank 2018a
Management of invasive species / encroachment	No global estimates	No evidence	
Restoration and reduced conversion of coastal wetlands	Very small negative impact but not quantified	Low confidence	
Restoration and reduced conversion of peatlands	Potential negative impact on 21-31 million people	Low confidence	Clark and Tilman 2017; FAO 2018
Biodiversity conservation	No global estimates	No evidence	

22

23 **6.3.5.1.5 Integrated response options based on land management specifically for CDR**

24 The spreading of crushed minerals on land as part of enhanced weathering on nutrient-depleted soils
25 can potentially increase crop yield by replenishing plant available silicon, potassium and other plant
26 nutrients (Beerling et al. 2018), but there are no estimates in the literature reporting the potential
27 magnitude of this effect on global food production.

28 Competition for land between bioenergy and food crops can lead to adverse side-effects for food
29 security. Many studies indicate that bioenergy could increase food prices (Calvin et al. 2014a; Popp et

1 al. 2017; Wise et al. 2009a). Only three studies were found linking bioenergy to the population at risk
2 of hunger; they estimate an increase in the population at risk of hunger of between 2 million and 150
3 million people (Table 6.49).

4 Table 6.49 summarises the impact on food security of response options specifically for CDR, with
5 confidence estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative
6 (not exhaustive) references upon which the evidence is based.

7 **Table 6.49 Effects on food security of response options specifically for CDR**

Integrated response option	Potential	Confidence	Citation

Bioenergy and BECCS	Negative impact on up to 150 million people	Medium confidence	Baldos and Hertel 2014a; Fujimori et al. 2018b

8 **6.3.5.2 Integrated response options based on value chain management**

9 In this section, the impacts on food security of integrated response options based on value change
10 management are assessed.

11 **6.3.5.2.1 Integrated response options based on value chain management through demand
12 management**

13 Dietary change can free up agricultural land for additional production (Bajželj et al. 2014; Stehfest et
14 al. 2009; Tilman and Clark 2014b) and reduce the risk of some diseases (Tilman and Clark 2014b;
15 Aleksandrowicz et al. 2016b) , with large positive impacts on food security (Table 6.50).

16 Kummu et al. (2012a) estimate that an additional billion people could be fed if food waste was halved
17 globally. This includes both post-harvest losses and retail and consumer waste, and measures such as
18 improved food transport and distribution could also contribute to this waste reduction (Table 6.50).

19 While no studies quantified the effect of material substitution on food security, the effects are
20 expected to be similar to reforestation and afforestation if the amount of material substitution leads to
21 an increase in forest area.

22 Table 6.50 summarises the impact on food security of demand management options, with confidence
23 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
24 exhaustive) references upon which the evidence is based.

25 **Table 6.50 Effects on food security of demand management options**

Integrated response option	Potential	Confidence	Citation
Dietary change	821 million people	High confidence	Aleksandrowicz et al. 2016b; Tilman and Clark 2014b
Reduced post-harvest losses	1000 million people	Medium confidence	Kummu et al. 2012
Reduced food waste (consumer or retailer)	700-1000 million people	Medium confidence	FAO 2018; Kummu et al. 2012
Material substitution	No global estimates	No evidence	

26
27 **6.3.5.2.2 Integrated response options based on value chain management through supply
28 management**

29 Since 810 million people are undernourished (FAO, 2018), this sets the maximum number of those
30 that could potentially benefit from sustainable sourcing or better management of supply chains.
31 Currently however, only 1 million people are estimated to benefit from sustainable sourcing (Tayleur

1 et al. 2017). For the latter, food price spikes affect food security and health; there are clearly
 2 documented effects of stunting among young children as a result of the 2007/2008 food supply crisis
 3 (de Brauw 2011; Arndt et al. 2012; Brinkman et al. 2010; Darnton-Hill and Cogill 2010) with a 10%
 4 increase in wasting attributed to the crisis in South Asia (Vellakkal et al. 2015). There is conflicting
 5 evidence on the impacts of different food price stability options for supply chains, and little
 6 quantification (Byerlee et al. 2006; del Ninno et al. 2007; Alderman 2010; Braun et al. 2014).
 7 Reduction in staple food prices due to price stabilisation resulted in more expenditure on other foods
 8 and increased nutrition (e.g., oils, animal products), leading to a 10% reduction in malnutrition among
 9 children in one study (Torlesse et al. 2003a). Comparison of two African countries shows that
 10 protectionist policies (food price controls) and safety nets to reduce price instability resulted in a 20%
 11 decrease in risk of malnutrition (Nandy et al. 2016). Models using policies for food aid and domestic
 12 food reserves to achieve food supply and price stability showed the most effectiveness of all options
 13 in achieving climate mitigation and food security goals (e.g. more effective than carbon taxes) as they
 14 did not exacerbate food insecurity and did not reduce ambitions for achieving temperature goals
 15 (Fujimori et al. 2018a).

16 For urban food systems, increased food production in cities combined with governance systems for
 17 distribution and access can improve food security, with a potential to produce 30% of food consumed
 18 in cities. The urban population in 2018 was 4.2 billion people, so 30% represents 1230 million people
 19 who could benefit in terms of food security from improved urban food systems (Table 6.51).

20 It is estimated that 500 million smallholder farmers depend on agricultural businesses in developing
 21 countries (World Bank, 2017), which sets the maximum number of people who could benefit from
 22 improved efficiency and sustainability of food processing, retail and agri-food industries.

23 Up to 2500 million people could benefit from increased energy efficiency in agriculture, based on the
 24 estimated number of people worldwide lacking access to clean energy and instead relying on biomass
 25 fuels for their household energy needs (IEA, 2014).

26 Table 6.51 summarises the impact on food security of supply management options, with confidence
 27 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
 28 exhaustive) references upon which the evidence is based.

29 **Table 6.51 Effects on food security of supply management options**

Management of supply chains	> 1 million people	Low confidence	FAO 2018; Kummu et al. 2012
Enhanced urban food systems	Up to 1260 million people	Low confidence	Benis and Ferrão 2017b; Padgham et al.; Specht et al. 2014; de Zeeuw & Drechsel 2015;
Improved food processing and retailing	500 million people	Low confidence	World Bank 2017
Improved energy use in food systems	Up to 2500 million people	Low confidence	IEA 2014

30

31 **6.3.5.3 Integrated response options based on risk management**

32 In this section, the impacts on food security of integrated response options based on risk management
 33 are assessed.

34 Evidence in the US indicates ambiguous trends between sprawl and food security; on one hand, most
 35 urban expansion in the US has primarily been on lands of low and moderate soil productivity with

1 only 6% of total urban land on highly productive soil. On the other hand, highly productive soils have
 2 experienced the highest rate of conversion of any soil type (Nizeyimana et al. 2001). Specific types of
 3 agriculture are often practiced in urban-influenced fringes, such as fruits, vegetables, and poultry and
 4 eggs in the US, the loss of which can have an impact on the types of nutritious foods available in
 5 urban areas (Francis et al. 2012b). China is also concerned with food security implications of urban
 6 sprawl, and a loss of 30 Mt of grain production from 1998–2003 in eastern China was attributed to
 7 urbanisation (Chen 2007b). However, overall global quantification has not been attempted.

8 Diversification is associated with increased welfare and incomes and decreased levels of poverty in
 9 several country studies (Arslan et al. 2018a; Asfaw et al. 2018). These are likely to have large food
 10 security benefits (Barrett et al. 2001; Niehof 2004), but there is little global quantification.

11 Local seed use can provide considerable benefits for food security because of the increased ability of
 12 farmers to revive and strengthen local food systems (McMichael and Schneider 2011b); studies have
 13 reported more diverse and healthy food in areas with strong food sovereignty networks (Coomes et al.
 14 2015b; Bisht et al. 2018). Women in particular may benefit from seed banks for low value but
 15 nutritious crops (Patnaik et al. 2017). Many hundreds of millions of smallholders still rely on local
 16 seeds and they provision many hundreds of millions of consumers (Altieri et al. 2012a; McGuire and
 17 Sperling 2016), so keeping their ability to do so through seed sovereignty is important. However,
 18 there may be lower food yields from local and unimproved seeds, so the overall impact of local seed
 19 use on food security is ambiguous (McGuire and Sperling 2016).

20 Disaster risk management approaches can have important impacts on reducing food insecurity, and
 21 current systems for drought warning and other storms currently reach over 100 million people. When
 22 these early warning systems can help farmers harvest crops in advance of impending weather events
 23 or otherwise make agricultural decisions to prepare for adverse events, there are likely to be positive
 24 impacts on food security (Fakhruddin et al. 2015). Surveys with farmers reporting food insecurity
 25 from climate impacts have indicated their strong interest in having such early warning systems
 26 (Shisanya and Mafongoya 2016). Additionally, famine early warning systems have been successful in
 27 Sahelian Africa to alert authorities of impending food shortages so that food acquisition and
 28 transportation from outside the region can begin, potentially helping millions of people (Genesio et al.
 29 2011; Hillbruner and Moloney 2012).

30 Risk sharing instruments are often aimed at sharing food supplies and reducing risk, and thus are
 31 likely to have important, but unquantified, benefits for food security. Crop insurance in particular has
 32 generally led to (modest) expansions in cultivated land area and increased food production (Claassen
 33 et al. 2011; Goodwin et al. 2004).

34 Table 6.52 summarises the impact on food security of risk management options, with confidence
 35 estimates based on the thresholds outlined in Table 6.53 in section 6.3.6, and indicative (not
 36 exhaustive) references upon which the evidence is based.

37 **Table 6.52 Effects on food security of risk management options**

Integrated response option	Potential	Confidence	Citation
Management of urban sprawl	>1 million likely	Low confidence	Bren d'Amour et al. 2016; Chen 2017
Livelihood diversification	>100 million	Low confidence	Morton 2007
Use of local seeds	>100 million	Low confidence	Altieri et al. 2012a
Disaster risk management	> 100 million	Medium confidence	Genesio et al. 2011; Hillbruner and Moloney 2012
Risk sharing instruments	>1 million likely	Low confidence	Claassen et al. 2011; Goodwin et al. 2004

6.3.6 Summarising the potential of the integrated response options across mitigation, adaptation, desertification land degradation and food security

Using the quantification provided in tables 6.13 to 6.52, the impacts are categorised as either positive or negative, and are designated as large, moderate and small according to the criteria given in Table 6.53⁶.

⁶ FOOTNOTE: Note that: 1) The response options often overlap, so are not additive. For example, increasing food productivity will involve changes to cropland, grazing land and livestock management, which in turn may include increasing soil carbon stocks. The response options cannot therefore be summed, nor regarded as entirely mutually exclusive interventions. 2) The efficacy of a response option for addressing the primary challenge for which it is implemented needs to be weighed against any co-benefits and adverse side-effects for the other challenges, e.g. if a response option has a major impact in addressing one challenge but results in relatively minor and manageable adverse-side effects for another challenge, it may remain a powerful response option despite the adverse side-effects, particularly if they can be minimised or managed. 3) Though the impacts of integrated response options have been quantified as far as possible in **Section 6.3**, there is no equivalence implied in terms benefits or adverse side-effects, either in number or in magnitude of the impact, i.e. one benefit *does not equal* one adverse side-effect. As a consequence: a) Large benefits for one challenge might outweigh relatively minor adverse side-effects in addressing another challenge, and b) Some response options may deliver mostly benefits with few adverse-side effects, but the benefits might be small in magnitude, i.e. the response options do no harm, but present only minor co-benefits. A number of benefits and adverse side-effects are context specific; the context specificity has been discussed in **section 6.2** and is further examined **Section 6.4.5.1**.

1 **Table 6.53 Key for criteria used to define magnitude of impact of each integrated response option**

	Mitigation	Adaptation	Desertification	Land Degradation	Food
Large positive	More than 3 GtCO ₂ -eq yr ⁻¹	Positively impacts more than around 25 million people	Positively impacts more than around 3 million km ²	Positively impacts more than around 3 million km ²	Positively impacts more than around 100 million people
Moderate positive	0.3 to 3 GtCO ₂ -eq	1 million to 25 million	0.5 to 3 million km ²	0.5 to 3 million km ²	1 million to 100 million
Small positive	>0	Under 1 million	>0	>0	Under 1 million
Negligible	0	No effect	No effect	No effect	No effect
Small negative	<0	Under 1 million	<0	<0	Under 1 million
Moderate negative	-0.3 to -3 GtCO ₂ -eq	1 million to 25 million	0.5 to 3 million km ²	0.5 to 3 million km ²	1 million to 100 million
Large negative	More than -3 GtCO ₂ -eq yr ⁻¹	Negatively impacts more than around 25 million people	Negatively impacts more than around 3 million km ²	Negatively impacts more than around 3 million km ²	Negatively impacts more than around 100 million people

2 **Note:** All numbers are for global scale; all values are for technical potential. For mitigation, the target is set at
3 around the level of large single mitigation measure (about 1 GtC yr⁻¹ = 3.67 GtCO₂-eq yr⁻¹) (Pacala and Socolow
4 2004), with a combined target to meet 100 GtCO₂ in 2100, to go from baseline to 2°C (Clarke and Jiang 2014b). For
5 adaptation, numbers are set relative to the about 5 million lives lost per year attributable to climate change and a
6 carbon-based economy, with 0.4 million per year attributable directly to climate change. This amounts to 100 million
7 lives predicted to be lost between 2010 and 2030 due to climate change and a carbon-based economy (DARA 2012),
8 with the largest category representing 25% of this total. For desertification and land degradation, categories are set
9 relative to the 10-60 million km² of currently degraded land (Gibbs and Salmon 2015) with the largest category
10 representing 30% of the lower estimate. For food security, categories are set relative to the roughly 800 million
11 people currently undernourished (HLPE 2017) with the largest category representing around 12.5% of this total.
12

13 Tables 6.54 to 6.61 summarise the potentials of the integrated response options across mitigation,
14 adaptation, desertification, land degradation and food security. Cell colours correspond to the large,
15 moderate and small impact categories shown in Table 6.53.

16 As seen in tables 6.54 to 6.61, three response options across the 14 for which there are data for every
17 land challenge: *increased food productivity*, *agroforestry* and *increased soil organic carbon content*,
18 deliver large benefits across all five land challenges.

19 A further six response options: *improved cropland management*, *improved grazing land management*,
20 *improved livestock management*, *agroforestry*, *fire management* and *reduced post-harvest losses*,
21 deliver either large or moderate benefits for all land challenges.

22 Three additional response options: *dietary change*, *reduced food waste* and *reduced soil salinisation*,
23 each missing data to assess global potential for just one of the land challenges, deliver large or
24 moderate benefits to the four challenges for which there are global data.

25 Eight response options: *increased food productivity*, *reforestation and forest restoration*,
26 *afforestation*, *increased soil organic carbon content*, *enhanced mineral weathering*, *dietary change*,

1 *reduced post-harvest losses, and reduced food waste, have large mitigation potential (>3 GtCO₂e yr⁻¹)*
2 *without adverse impacts on other challenges.*

3 *Sixteen response options: increased food productivity, improved cropland management, agroforestry,*
4 *agricultural diversification, improved forest management, increased soil organic carbon content,*
5 *reduced landslides and natural hazards, restoration and reduced conversion of coastal wetlands,*
6 *reduced post-harvest losses, sustainable sourcing, management of supply chains, improved food*
7 *processing and retailing, improved energy use in food systems, livelihood diversification, use of local*
8 *seeds, and disaster risk management, have large adaptation potential at global scale (positively*
9 *affecting >25 million people) without adverse side-effects for other challenges.*

10 Thirty-three of the 40 response options can be applied without requiring land use change and limiting
11 available land. A large number of response options do not require dedicated land, including several
12 land management options, all value chain options, and all risk management options. Four options, in
13 particular, could greatly increase competition for land if applied at scale: *afforestation, reforestation,*
14 *and land used to provide feedstock for bioenergy (with or without BECCS) and biochar, with three*
15 *further options: reduced grassland conversion to croplands, restoration and reduced conversion of*
16 *peatlands and restoration and reduced conversion of coastal wetlands having smaller or variable*
17 *impacts on competition for land. Other options such as reduced deforestation and degradation,*
18 *restrict land conversion for other options and uses.*

19 Some response options can be more effective when applied together; for example, dietary change and
20 waste reduction expand the potential to apply other options by freeing as much as 25 Mkm² (4-25
21 Mkm² for dietary change; Alexander et al. 2016; Bajželj et al. 2014; Stehfest et al. 2009; Tilman and
22 Clark 2014b and 7 Mkm² for reduced food waste; Bajželj et al. 2014).

23 In terms of the categories of response options, most agricultural land management response options
24 (all except for reduced grassland conversion to cropland which potentially adversely affects food
25 security), deliver benefits across the five land challenges (Table 6.54). Among the forest land
26 management options, afforestation and reforestation have the potential to deliver large co-benefits
27 across all land challenges except for food security, where these options provide a threat due to
28 competition for land (Table 6.55). Among the soil-based response options, some global data are
29 missing, but none except biochar shows any potential for negative impacts, with that potential
30 negative impact arising from additional pressure on land if large quantities of biomass feedstock are
31 required for biochar production (Table 6.56). Where global data exists, most response options in
32 other/all ecosystems deliver benefits except for a potential moderate negative impact on food security
33 by restoring peatlands currently used for agriculture (Table 6.57). Of the two response options
34 specifically targeted at CDR, there are missing data for enhanced weathering of minerals for three of
35 the challenges, but large-scale bioenergy and BECCS shows a potential large benefit for mitigation,
36 but small to large adverse impacts on the other four land challenges (Table 6.58), mainly driven by
37 increased pressure on land due to feedstock demand.

38 While data allow the impact of material substitution to be assessed only for mitigation, the three other
39 demand-side response options: dietary change, reduced post-harvest losses and reduced food waste
40 provide large or moderate benefits across all challenges for which data exist (Table 6.59). For none of
41 the supply-side response options is data available to assess the impact on more than three of the land
42 challenges, but there are large to moderate benefits for all those for which data are available (Table
43 6.60). Data are not available to assess the impact of risk management-based response options on all of
44 the challenges, but there are small to large benefits for all of those for which data are available (Table
45 6.61).

1 **Table 6.54 Summary of direction and size of impact of land management options in agriculture on mitigation, adaptation, desertification, land degradation and**
2 **food security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	
Increased food productivity						<p>Context and evidence base for magnitude of effect</p> <p>These estimates assume that increased food production is implemented sustainably (e.g. through sustainable intensification: Garnett et al. 2013b; Pretty et al. 2018) rather than through increasing external inputs, which can have a range of negative impacts. <u>Mitigation</u>: Large benefits (Table 6.13). <u>Adaptation</u>: Large benefits (Chapter 2; Table 6.21; Campbell et al. 2014). <u>Desertification</u>: Large benefits (Chapter 3; Table 6.29; Dai 2010). <u>Land degradation</u>: Large benefits (Chapter 4; Table 6.37; Clay et al., 1995). <u>Food security</u>: Large benefits (Chapter 5; Table 6.45; Godfray et al. 2010b; Tilman et al. 2011; Godfray and Garnett 2014).</p>
Improved cropland management						<p><u>Mitigation</u>: Moderate benefits by reducing greenhouse gas emissions and creating soil carbon sinks (Chapter 2; Table 6.13; Smith et al. 2008, 2014a). <u>Adaptation</u>: Large benefits by improving the resilience of food crop production systems to future climate change (Chapter 2; Table 6.21; Porter et al. 2014). <u>Desertification</u>: Large benefits by improving sustainable use of land in dry areas (Chapter 3; Table 6.29; Bryan et al. 2009b; Chen et al. 2010). <u>Land degradation</u>: Large benefits by forming a major component of sustainable land management (Chapter 4; Table 6.37; Labrière et al. 2015). <u>Food security</u>: Large benefits by improving agricultural productivity for food production (Chapter 5; Table 6.45; Porter et al. 2014).</p>
Improved grazing land management						<p><u>Mitigation</u>: Moderate benefits by increasing soil carbon sinks and reducing greenhouse gas emissions (Chapter 2; Table 6.13; Herrero et al. 2016). <u>Adaptation</u>: Moderate benefits by improving the resilience of grazing lands to future climate change (Chapter 2; Table 6.21; Porter et al. 2014). <u>Desertification</u>: Moderate benefits by tackling overgrazing in dry areas to reduce desertification (Chapter 3; Table 6.29; Archer et al. 2011). <u>Land degradation</u>: Large benefits by optimising stocking density to reduce land degradation (Chapter 4; Table 6.37; Table 6.45; Tighe et al. 2012). <u>Food security</u>: Large benefits by improving livestock sector productivity to increase food production (Chapter 5; Table 6.45; Herrero et al. 2016).</p>
Improved livestock management						<p><u>Mitigation</u>: Moderate benefits by reducing greenhouse gas emissions, particularly from enteric methane and manure management (Chapter 2; Table 6.13; Smith et al. 2008, 2014a). <u>Adaptation</u>: Moderate benefits by improving resilience of livestock production systems to climate change (Chapter 2; Table 6.21; Porter et al. 2014). <u>Desertification</u>: Moderate benefits by tackling overgrazing in dry areas (Chapter 3; Table 6.29; Archer et al. 2011). <u>Land degradation</u>: Large benefits by reducing overstocking which can reduce land degradation (Chapter 4; Table 6.37; Table 6.45; Tighe et al. 2012). <u>Food security</u>: Large benefits by improving livestock sector productivity to increase food production (Chapter 5; Table 6.45; Herrero et al. 2016).</p>
Agroforestry						<p><u>Mitigation</u>: Moderate benefits by increasing carbon sinks in vegetation and soils (Chapter 2; Table 6.13; Delgado 2010; Mbow et al. 2014a; Griscom et al. 2017a). <u>Adaptation</u>: Large benefits by improving the resilience of agricultural lands to climate change (Chapter 2; Table 6.21; Mbow et al. 2014a). <u>Desertification</u>: Large benefits through e.g. provides perennial vegetation in dry areas (Chapter 3; Table 6.29; Nair et al. 2010; Lal 2001a). <u>Land degradation</u>: Large benefits by stabilising soils through perennial</p>

						vegetation (Chapter 4; Table 6.37; Narain et al. 1997; Lal 2001a). Food production: <i>Large benefits</i> since well-planned agroforestry can enhance productivity (Chapter 5; Table 6.45; Bustamante et al. 2014b; Sasha et al., 2018).
Agricultural diversification						Agricultural diversification is a collection of practices aimed at deriving more crops or products per unit of area (e.g. intercropping) or unit of time (e.g. double cropping, ratoon crops etc.). Mitigation: <i>Limited benefits</i> (Table 6.13). Adaptation: <i>Large benefits</i> through improved household income (Pellegrini and Tasciotti 2014; Table 6.21). Desertification: <i>Moderate benefits</i> , limited by global dryland cropped area (Table 6.29). Land degradation: <i>Large benefits</i> by reducing pressure on land (Table 6.37; Lambin and Meyfroidt 2011). Food security: <i>Large benefits</i> for food security by provision of more diverse foods (Chapter 5; Table 6.45; Birthal et al. 2015; Massawe et al. 2016; Waha et al. 2018).
Reduced grassland conversion to cropland		N D				Mitigation: <i>Moderate benefits</i> by retaining soil carbon stocks that might otherwise be lost. Historical losses of soil carbon have been on the order of 500 GtCO ₂ (Table 6.13; Sanderman et al. 2017). Mean annual global cropland conversion rates (1961–2003) have been 0.36% per year (Krause et al. 2017), i.e. around 47 thousand km ² yr ⁻¹ – so preventing conversion could potentially save moderate emissions of CO ₂ . Adaptation: No literature (Table 6.21). Desertification: <i>Limited benefits</i> by shifting from annual crops to permanent vegetation cover under grass in dry areas (Chapter 3; Table 6.29). Land degradation: <i>Limited benefits</i> by shifting from annual crops to permanent vegetation cover under grass (Chapter 4; Table 6.37). Food security: <i>Moderate negative impacts</i> , since more land is required to produce human food from livestock products on grassland than from crops on cropland, meaning that a shift to grassland could reduce total productivity and threaten food security (Chapter 5; Table 6.45; Clark and Tilman 2017).
Integrated water management						Mitigation: <i>Moderate benefits</i> by reducing greenhouse gas emissions mainly in cropland and rice cultivation (Chapter 2; Table 6.13; Smith et al. 2008, 2014a). Adaptation: <i>Large benefits</i> by improving the resilience of food crop production systems to future climate change (Chapter 2; Table 6.21; Porter et al. 2014). Desertification: <i>Limited benefits</i> by improving sustainable use of land in dry areas (Chapter 3; Table 6.29). Land degradation: <i>Limited benefits</i> by forming a major component of sustainable land and water management (Chapter 4; Table 6.37). Food security: <i>Large benefits</i> by improving agricultural productivity for food production (Chapter 5; Table 6.45; Tilman et al. 2011; Godfray and Garnett 2014).

1 **Note:** Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
 2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.
 3

4 **Table 6.55 Summary of direction and size of impact of land management options in forests on mitigation, adaptation, desertification, land degradation and food**
 5 **security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	Context and evidence base for magnitude of effect
Improved forest						Mitigation: <i>Moderate benefits</i> by conserving and enhancing carbon stocks in forests and long-lived products, through for example, selective logging (Table 6.14; Smith et al. 2014a). Adaptation: <i>Large benefits</i> , including through improving ecosystem

management	Light Blue	Dark Blue	Dark Blue	Dark Blue	Light Blue	functionality and services, with mostly qualitative evidence at global scale and more robust estimates at regional level and local scale (Table 6.22; Locatelli et al. 2015d). <u>Desertification and land degradation</u> : Large benefits by helping to stabilise land and regulate water and microclimate (Chapters 3 and 4; Tables 6.30 and 6.38; Locatelli et al. 2015d). <u>Food security</u> : Moderate benefits with mostly qualitative estimate at global level, by providing food to local communities, and diversify daily diets (Chapter 5; Table 6.46).
Reduced deforestation and degradation	Dark Blue	Light Blue	Dark Blue	Dark Blue	Light Blue	<u>Mitigation</u> : Large benefits by maintaining carbon stocks in forest ecosystems (Chapter 2; Table 6.14). <u>Adaptation</u> Moderate benefits at global scale when effect is cumulated till the end of the century; local scale, co-benefits between REDD+ and adaptation of local communities can be more substantial (Long 2013; Morita & Matsumoto 2017), even if often difficult to quantify and not explicitly acknowledged (McElwee et al. 2017a; Table 6.22). <u>Desertification and land degradation</u> : Large benefits at global scale when effects are cumulated for at least 20 years, e.g. through reduced soil erosion (Borrelli et al. 2017; Tables 6.30 and 6.38). The uncertainty of these global estimates is high, while more robust qualitative and some quantitative estimates are available at regional level. <u>Food security</u> : Small benefits ; difficult to quantify at global level (Chapter 5; Table 6.46).
Reforestation and forest restoration	Dark Blue	Dark Blue	Dark Blue	Dark Blue	Orange	<u>Mitigation</u> : Large benefits by rebuilding the carbon stocks in forest ecosystems, although decreases in surface albedo can reduce the net climate benefits, particularly in areas affected by seasonal snow cover (Chapter 2; Table 6.14; Sonntag et al. 2016; Mahmood et al. 2014). <u>Adaptation</u> : Large benefits by provision of Nature’s Contributions to People, including improving ecosystem functionality and services, providing microclimatic regulation for people and crops, wood and fodder as safety nets, soil erosion protection and soil fertility enhancement for agricultural resilience, coastal area protection, water and flood regulation (Locatelli et al. 2015d; Table 6.22). <u>Desertification</u> : Large benefits through restoring forest ecosystems in dryland areas (Chapter 3; Table 6.30; Idris Medugu et al. 2010a; Salvati et al. 2014b). <u>Land degradation</u> : Large benefits by re-establishment of perennial vegetation (Chapter 4; Table 6.38; Ellison et al. 2017b). <u>Food security</u> : Moderate negative impacts due to potential competition for land for food production (Chapter 5; Table 6.46; Frank et al. 2017).
Afforestation	Dark Blue	Dark Blue	Dark Blue	Dark Blue	Dark Orange	<u>Mitigation</u> : Large benefits for mitigation (Chapter 2; Table 6.14), especially if it occurs in the tropics and in areas that are not significantly affected by seasonal snow cover. <u>Adaptation</u> : Large benefits on adaptation (Chapter 2; Table 6.22; Kongsager et al. 2016; Reyer et al. 2009). <u>Desertification</u> : Large benefits by providing perennial vegetation in dry areas to help control desertification (Chapter 3; Table 6.30; Idris Medugu et al. 2010a; Salvati et al. 2014b). <u>Land degradation</u> : Large benefits by stabilising soils through perennial vegetation (Chapter 4; Table 6.38; Lal 2001a). <u>Food security</u> : Large negative impacts due to competition for land for food production (Chapter 5; Table 6.46; Kreidenweis et al. 2016b; Smith et al. 2013b).

1 Note: Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
 2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.

3 **Table 6.56 Summary of direction and size of impact of soil-based land management options on mitigation, adaptation, desertification, land degradation and food**
 4 **security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	
						Context and evidence base for magnitude of effect
Increased soil organic carbon content						<u>Mitigation</u> : Large benefits by creating soil carbon sinks (Table 6.15). <u>Adaptation</u> : Large benefits by improving resilience of food crop production systems to climate change (Chapter 2; Table 6.24; IPBES 2018). <u>Desertification</u> : Large benefits by improving soil health and sustainable use of land in dry areas (Chapter 3; Table 6.31; D’Odorico et al. 2013). <u>Land degradation</u> : Large benefits since it forms a major component of recommended practices for sustainable land management (Chapter 4; Table 6.39; Altieri and Nicholls 2017). <u>Food security</u> : Large benefits since it can increase yield and yield stability to enhance food production, though this is not always the case (Chapter 5; Table 6.47; Pan et al. 2009; Soussana et al. 2019; Hijbeek et al., 2017; Schjøning et al., 2018).
Reduced soil erosion						<u>Mitigation</u> : Large benefits or large negative impacts , since the final fate of eroded material is still debated, at the global level it is debated whether it is a large source or a large sink (Chapter 2; Table 6.15; Hoffmann et al. 2013). <u>Adaptation</u> : Large benefits since soil erosion control prevents <u>desertification</u> (large benefits) and <u>land degradation</u> (large benefits), thereby improving the resilience of agriculture to climate change (Chapter 2, 3 and 4; Table 6.23, 6.30 and 6.39; Lal 1998; FAO and ITPS 2015). <u>Food security</u> : Large benefits mainly through the preservation of crop productivity (Chapter 5; Table 6.47; Lal 1998).
Reduced soil salinisation	N D					Techniques to prevent and reverse soil salinisation include groundwater management by drainage systems and/or crop rotation and use of amendments to alleviate soil sodicity. <u>Mitigation</u> : There are no studies to quantify the global impacts (Table 6.15). <u>Adaptation</u> : Moderate benefits by allowing existing crop systems to be maintained, reducing the need to abandon land (Table 6.23; UNCTAD 2011; Dagar et al. 2016b). <u>Desertification</u> and <u>land degradation</u> : Moderate benefits since soil salinisation is a main driver of both desertification and land degradation (Chapters 3 and 4; Tables 6.31 and 6.39; Rengasamy 2006; Dagar et al. 2016b). <u>Food security</u> : Moderate benefits by maintaining existing cropping systems and helping to close yield gaps in rainfed crops (Table 6.47).
Reduced soil compaction	N D		N D			Techniques to prevent and reverse soil compaction are based on the combination of suitable crop rotations, tillage and regulation of agricultural traffic (Hamza and Anderson 2005b). <u>Mitigation</u> : The global mitigation potential has not been quantified (Table 6.15; Chamen et al. 2015a; Epron et al. 2016; Tullberg et al. 2018b). <u>Adaptation</u> : Limited benefits by improving productivity but on relatively small global areas (Table 6.22). <u>Desertification</u> : no global data (Table 6.31). <u>Land degradation</u> : Large benefits since soil compaction is a main driver of land degradation (Table 6.39; FAO and ITPS 2015). <u>Food security</u> : Moderate benefits by helping to close yield gaps where compaction is a limiting factor (Table 6.47; Anderson and Peters 2016).
Biochar addition to soil		N D	N D			<u>Mitigation</u> : Large benefits by increasing recalcitrant carbon stocks in the soil (Chapter 2; Table 6.15; Smith 2016b; Fuss et al. 2018b; IPCC 2018). <u>Adaptation</u> : There are no global estimates of the impact of biochar on climate adaptation (Table 6.23). <u>Desertification</u> : There are no global estimates of the impact of biochar on desertification (Table 6.31). <u>Land degradation</u> : Limited benefits by improving the soil water holding capacity, nutrient use efficiency, and potentially ameliorating heavy metal pollution (Table 6.39; Sohi 2012). <u>Food security</u> : Limited benefits by increasing crop yields in the tropics (though not in temperate regions; Jeffery et al. 2017), but potentially Large negative impacts by creating additional pressure on land if large quantities of biomass

feedstock are required for biochar production (Table 6.47).

1 Note: Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.

3 **Table 6.57 Summary of direction and size of impact of land management in all/other ecosystems on mitigation, adaptation, desertification, land degradation and**
4 **food security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	Context and evidence base for magnitude of effect
Fire management	Dark blue	Light blue	Dark blue	Dark blue	Light blue	<u>Mitigation:</u> Large benefits by reduced size, severity, and frequency of wildfires, thereby preventing emissions and preserving carbon stocks (Table 6.16; Chapter 2, Cross-Chapter Box 3; Arora and Melton 2018). <u>Adaptation:</u> Moderate benefits by reducing mortality attributable to landscape fire smoke exposure, fire management provides adaptation benefits (Table 6.24; Doerr and Santín 2016; Johnston et al. 2012; Shannon et al., 2016). <u>Desertification:</u> Large benefits since control of wildfires and long-term maintenance of tree stock density protects against soil erosion (Table 6.32; Neary et al. 2009a; Arora and Melton 2018). <u>Land degradation:</u> Large benefits by stabilising forest ecosystems (Table 6.40; Neary et al. 2009a; Arora and Melton 2018). <u>Food security:</u> Moderate benefits by maintaining forest food product availability and preventing fire expansion to agricultural land (Table 6.48; FAO 2015; FAO 2018; FAO et al., 2018; Pradhan et al., 2013; World Bank 2018a,b).
Reduced landslides and natural hazards	Light blue	Dark blue	Light blue	Dark blue	Light blue	<u>Mitigation:</u> The prevention of landslides and natural hazards benefits mitigation, but because of the limited impact on GHG emissions and eventual preservation of topsoil carbon stores, the impact is estimated to be small globally (Table 6.16; IPCC AR5 WG2, Chapter 14). <u>Adaptation:</u> Provides structural/physical adaptations to climate change (Table 6.24; IPCC AR5 WG2, Chapter 14). <u>Desertification:</u> Due to the small global areas affected within global drylands, the benefits for desertification control are limited (Chapter 3; Table 6.32). <u>Land degradation:</u> Since landslides and natural hazards are among the most severe degradation processes, prevention will have a large positive impact on land degradation (Chapter 4; Table 6.40; FAO and ITPS 2015). <u>Food security:</u> In countries in which mountain slopes are cropped for food, such as in the Pacific Islands (Campbell 2015), the management and prevention of landslides can deliver benefits for food security, though the global areas are limited (Table 6.48).
Reduced pollution including acidification	Green	Light blue	Light blue	Light blue	Dark blue	<u>Mitigation:</u> Large benefits since measures to reduce emissions of Short-Lived Climate Pollutants (SLCPs) can slow projected global mean warming (UNEP and WMO 2011), with early intervention providing 0.5°C cooling by 2050 (Table 6.16; UNEP and WMO 2011). But moderate negative impacts are also possible since reduced reactive N deposition could decrease terrestrial carbon uptake (Table 6.16). <u>Adaptation:</u> Moderate benefits since controlling PM2.5 and ozone improves human health (Table 6.24; Anenberg et al. 2012). <u>Desertification:</u> Moderate benefits since salinisation, pollution, and acidification are stressors for desertification (Table 6.32; Oldeman et al. 1991). <u>Land degradation:</u> Moderate benefits since acid deposition is a significant driver of land degradation (Table 6.40; Oldeman et al. 1991; Smith et al. 2015). <u>Food security:</u> Large benefits since ozone is harmful to crops, so measures to reduce air pollution would be expected to increase crop production (Table 6.48; Shindell et al. 2012; Pradhan

						et al., 2013; FAO, 2018; FAO et al., 2018; World Bank 2018a).
Management of invasive species / encroachment	N D	N D	N D	N D	N D	There is no literature that assesses the global potential of management of invasive species on <u>mitigation, adaptation, desertification, land degradation</u> or on <u>food security</u> (Table 6.16; Table 6.24; Table 6.33; Table 6.40; Table 6.48).
Restoration and reduced conversion of coastal wetlands						<u>Mitigation: Large benefits</u> since coastal wetland restoration and avoided coastal wetland impacts deliver moderate carbon sinks by 2030 (Table 6.16; Griscom et al. 2017a). <u>Adaptation: Large benefits</u> by providing a natural defence against coastal flooding and storm surges by dissipating wave energy, reducing erosion and by helping to stabilise shore sediments (Table 6.24). <u>Desertification:</u> There is likely negligible impact of coastal wetland restoration for prevention of desertification (Table 6.32). <u>Land degradation:</u> Limited benefits since large areas of global coastal wetlands are degraded (Lotze et al. 2006; Griscom et al. 2017a; Table 6.40). <u>Food security: Small benefits to small adverse impacts</u> since large areas of converted coastal wetlands are used for food production (e.g. mangroves converted for aquaculture), restoration could displace food production and damage local food supply, though mangrove restoration can also restore local fisheries (Table 6.48; Naylor et al. 2000b).
Restoration and reduced conversion of peatlands		N D				<u>Mitigation: Moderate benefits</u> since avoided peat impacts and peat restoration deliver moderate carbon sinks by 2030 (Table 6.16; Griscom et al. 2017a), though there can be increases in methane emissions after restoration (Jauhiainen et al. 2008). <u>Adaptation:</u> Likely to be benefits by regulating water flow and preventing downstream flooding (Table 6.24; Munang et al. 2014a), but the global potential has not been quantified. <u>Desertification:</u> No impact since peatlands occur in wet areas and deserts in dry areas. <u>Land degradation: Moderate benefits</u> since large areas of global peatlands are degraded (Table 6.40; Griscom et al. 2017a). <u>Food security: Moderate adverse impacts</u> since restoration of large areas of tropical peatlands and some northern peatlands that have been drained and cleared for food production, could displace food production and damage local food supply (Table 6.48).
Biodiversity conservation			N D	N D	N D	<u>Mitigation: Moderate benefits</u> from carbon sequestration in protected areas (Table 6.16; Calvin et al. 2014a). <u>Adaptation: Moderate benefits</u> – likely many millions benefit adaptation and resilience of local communities to climate change (Table 6.24; CBD, 2008), though global potential is poorly quantified. <u>Desertification:</u> No global data (Table 6.32). <u>Land degradation:</u> No global data (Table 6.40). <u>Food security:</u> No global data (Table 6.48).

1 Note: Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.

3 **Table 6.58 Summary of direction and size of impact of land management options specifically for CDR on mitigation, adaptation, desertification, land degradation
4 and food security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	Context and evidence base for magnitude of effect
Enhanced		N	N		N	<u>Mitigation: Moderate to large benefits</u> by removing atmospheric CO ₂ (Table 6.17; Lenton 2010; Smith et al. 2016b; Taylor et al.

weathering of minerals		D	D		D	2016b). Adaptation: There is no literature to assess the global impacts of enhanced mineral weathering on adaptation (Table 6.25) nor on desertification (Table 6.33). Land degradation: <i>Limited benefits</i> expected since ground minerals can increase pH where acidification is the driver of degradation (Table 6.41; Taylor et al. 2016b). Food security: Though there may be co-benefits for food production (Beerling et al. 2018), these have not been quantified globally (Table 6.49).
Bioenergy and BECCS						Mitigation: <i>Large benefits</i> of large-scale bioenergy and BECCS by potential to remove large quantities of CO ₂ from the atmosphere (Table 6.17). Adaptation: <i>Limited adverse impacts</i> of large-scale bioenergy and BECCS by increasing pressure on land (Table 6.25). Desertification: Moderate adverse impacts of large-scale bioenergy and BECCS through increased pressure on land (Table 6.33). Land degradation: <i>Large adverse impacts</i> of large-scale bioenergy and BECCS through increased pressure on land (Table 6.41). Food security: <i>Large adverse impacts</i> of large-scale bioenergy and BECCS through increased competition for land for food (Table 6.49). These potentials and effects assume large areas of bioenergy crops resulting in large mitigation potentials (i.e. >3 GtCO ₂ yr ⁻¹). The sign and magnitude of the effects of bioenergy and BECCS depends on the scale of deployment, the type of bioenergy feedstock, which other response options are included, and where bioenergy is grown (including prior land use and indirect land use change emissions). For example, limiting bioenergy production to marginal lands or abandoned cropland would have negligible effects on biodiversity, food security, and potentially small co-benefits for land degradation; however, the benefits for mitigation would also be smaller (Cross-Chapter Box 7 on Bioenergy (Chapter 6); Table 6.13).

1 Note: Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
 2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.
 3

4 **Table 6.59 Summary of direction and size of impact of demand management options on mitigation, adaptation, desertification, land degradation and food security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	Context and evidence base for magnitude of effect
Dietary change		N D				Mitigation: <i>Large benefits</i> for mitigation by greatly reducing GHG emissions (Chapter 5; Table 6.18). Adaptation: While it would be expected to help with adaptation by reducing agricultural land area, there are no studies providing global quantifications (Table 6.26). Desertification: Potential <i>moderate benefits</i> by decreasing pressure on land (restricted by relatively limited global area; Table 6.34). Land degradation: <i>Large benefits</i> by decreasing pressure on land (Table 6.42). Food security: Large benefits by decreasing competition for land allowing more food to be produced from less land (Table 6.50).
Reduced post-harvest losses						Mitigation: <i>Large benefits</i> by reducing food sector GHG emissions and reducing area required to produce the same quantity of food (Table 6.18), though increased use of refrigeration could increase emissions from energy use. Adaptation: <i>Large benefits</i> by reducing pressure on land (Table 6.26). Desertification and land degradation: <i>Moderate benefits</i> for both by reducing pressure on land (Table 6.34; Table 6.42). Food security: <i>Large benefits</i> since most of the food wasted in developing countries arises from post-harvest losses (Chapter 5; Table 6.50; Ritzema et al. 2017).

Reduced food waste (consumer or retailer)		N D				Mitigation: <i>Large benefits</i> by reducing food sector GHG emissions and reducing area required to produce the same quantity of food (Table 6.18). Adaptation: While it would be expected to help with adaptation by reducing agricultural land area, there are no studies quantifying global adaptation impacts (Table 6.26). Desertification: <i>Moderate benefits</i> by reducing pressure on land (Table 6.34). Land degradation: <i>Large benefits</i> by reducing pressure on land (Table 6.42). Food security: <i>Large benefits</i> since 30% of all food produced globally is wasted (Table 6.50; Kummu et al. 2012).
Material substitution		N D	N D	N D	N D	Mitigation: <i>Moderate benefits</i> through long-lived carbon storage, and by substitution of materials with higher embedded GHG emissions (Table 6.18). No global studies available to assess the quantitative impact on adaptation, desertification, land degradation or food security (Table 6.26; Table 6.34; Table 6.42; Table 6.50).

1 **Note:** Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.
3

3

4 **Table 6.60 Summary of direction and size of impact of supply management options on mitigation, adaptation, desertification, land degradation and food security**

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	Context and evidence base for magnitude of effect
Sustainable sourcing	N D		N D			Mitigation: No studies available to assess the global impact (Table 6.19). Adaptation: <i>Moderate benefits</i> by diversifying and increasing flexibility in the food system to climate stressors and shocks while simultaneously creating economic alternatives for the poor (thereby strengthening adaptive capacity) and lowering expenditures of food processors and retailers by reducing losses (Chapter 5; Table 6.27; Muller et al. 2017a). Desertification: No studies available to assess the global impact (Table 6.35; Table 6.43). Land degradation: Potentially <i>large benefits</i> , as over 4 Mkm ² currently certified for sustainable forest production, which could increase in future (Table 6.44). Food security: <i>Moderate benefits</i> by diversifying markets and developing value-added products in the food supply system, by increasing its economic performance and revenues to local farmers (Reidsma et al. 2010), by strengthening the capacity of food production chains to adapt to future markets and to improve income of smallholder farmers (Chapter 5; Table 6.51; Murthy and Madhava Naidu 2012). It may also provide more direct links between producers and consumers.
Management of supply chains	N D		N D	N D		Mitigation: There are no studies assessing the mitigation potential globally (Table 6.19). Adaptation: <i>Large benefits</i> by improving resilience to price increases or reducing volatility of production (Table 6.27; Fafchamps et al. 1998; Haggblade et al. 2017). Desertification and land degradation: No studies assessing global potential (Table 6.35; Table 6.43). Food security: <i>Moderate benefits</i> through helping to manage food price increases and volatility (Table 6.51; Vellakkal et al. 2015; Arndt et al. 2016).
Enhanced urban food	N D	N D	N D	N D		There are no studies that assess the global potential to contribute to mitigation, adaptation, desertification or land degradation (Table 6.19; Table 6.27; Table 6.35; Table 6.43). Food security: <i>Large benefits</i> by increasing food access to urban dwellers and

systems						shortening of supply chains (Chapter 5; Table 6.51; Chappell et al. 2016).
Improved food processing and retailing			N D	N D		<u>Mitigation</u> : Moderate benefits through reduced energy consumption, climate-friendly foods and reduced GHG emissions from transportation (Avetisyan et al. 2014), waste (Porter et al. 2016b), and energy use (Table 6.19; Mohammadi et al. 2014; Song et al. 2017). <u>Adaptation</u> : Large benefits among poor farmers through reduced costs and improved resilience (Table 6.27). <u>Desertification</u> and <u>land degradation</u> : There are no studies assessing global potential (Table 6.35; Table 6.43). <u>Food security</u> : Large benefits by supporting healthier diets and reducing food loss and waste (Chapter 5; Table 6.51; Garnett 2011).
Improved energy use in food systems			N D	N D		<u>Mitigation</u> : Moderate benefits by reducing GHG emissions through decreasing use of fossil fuels and energy-intensive products, though the emission reduction is not accounted for in the AFOLU sector (Table 6.19; Smith et al. 2014a; IPCC AR5 WG3 Chapter 11). <u>Adaptation</u> : Large benefits for small farmers by reducing costs and increasing their resilience to climate change (Table 6.27). <u>Desertification</u> and <u>land degradation</u> : There are no studies assessing global potential (Table 6.35; Table 6.43). <u>Food security</u> : Large benefits , largely by improving efficiency for 2.5 million people still using traditional biomass for energy (Chapter 5; Table 6.51).

1 Note: Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
 2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.

Table 6.61 Summary of direction and size of impact of risk management options on mitigation, adaptation, desertification, land degradation and food security

Integrated response option	Mitigation	Adaptation	Desertification	Land degradation	Food security	Context and evidence base for magnitude of effect
Management of urban sprawl	N D					<u>Mitigation</u> : There are no studies assessing the global potential (Table 6.20). <u>Adaptation</u> : Moderate benefits - though poorly quantified globally, likely to affect many millions of people (Table 6.28). <u>Desertification</u> : Limited benefits - though poorly quantified globally, 5000 km ² is at risk from urban sprawl in Spain alone; (Table 6.36). <u>Land degradation</u> : Limited benefits - though poorly quantified globally, urban sprawl effects millions of ha of land (Table 6.44). <u>Food security</u> : Moderate benefits estimated from impacts on food supply in models (Table 6.52; Bren d'Amour et al. 2016).
Livelihood diversification	N D					<u>Mitigation</u> : There are no studies assessing the global potential (Table 6.20). <u>Adaptation</u> : Large benefits through helping households to buffer income fluctuations and providing a broader range of options for the future (Table 6.28; Ahmed and Stepp 2016b; Thornton and Herrero 2014). <u>Desertification</u> : There are no studies assessing the global potential, although there are anecdotal reports of limited benefits from improved land management resulting from diversification (Batterbury 2001; Herrmann and Hutchinson 2005; Stringer et al. 2009) (Table 6.36). <u>Land degradation</u> : Limited benefits , for example through improved land use mosaics (Ribeiro et al 2013), larger-scale adoption in China's Sloping Land Conversion program to diversify income and reduce degradation has impacted 0.1 Mkm ² (Liu and Lan 2015; Table 6.44). <u>Food security</u> : Large benefits since many of the world's 700 million smallholders practice diversification, helping to provide economic access to food (Table 6.52; Morton 2007).

Use of local seeds	N D		N D	N D		<p><u>Mitigation</u>: There are no studies assessing the global potential (Table 6.19). <u>Adaptation</u>: Large benefits given that 60 to 100% of seeds used in various countries of the global South are likely local farmer-bred (non-commercial) seed and moving to the use of commercial seed would increase costs considerably for these farmers. Seed networks and banks protect local agrobiodiversity and landraces, which are important to facilitate adaptation, and can provide crucial lifelines when crop harvests fail (Table 6.28; Louwaars 2002; Howard 2015; Coomes et al. 2015b; van Niekerk and Wynberg 2017b; Vasconcelos et al. 2013; Reisman 2017). <u>Desertification</u> and <u>land degradation</u>: There are no studies assessing global potential (Table 6.36; Table 6.44). <u>Food security</u>: Large benefits since local seeds increases the ability of farmers to revive and strengthen local food systems; several studies have reported more diverse and healthy food in areas with strong food sovereignty networks (Table 6.52; Coomes et al. 2015b; Bisht et al. 2018).</p>
Disaster risk management	N D		N D	N D		<p><u>Mitigation</u>: There are no studies to assess the global mitigation potential of different DRM approaches (Table 6.19). <u>Adaptation</u>: Large benefits due to widespread use of Early Warning Systems that reach hundreds of millions (Table 6.28; Hillbruner and Moloney 2012; Mahmud and Prowse 2012; Birkmann et al. 2015b). <u>Desertification</u> and <u>land degradation</u>. There are no studies assessing the global potential (Table 6.36; Table 6.44). <u>Food security</u>: Moderate benefits by helping farmers to harvest crops in advance of impending weather events or otherwise to make agricultural decisions to prepare for adverse events (Table 6.52; Fakhruddin et al. 2015; Genesio et al. 2011; Hillbruner and Moloney 2012).</p>
Risk sharing instruments			N D			<p><u>Mitigation</u>: Variable impacts- poor global coverage in the literature though studies from the US suggest a small increase in emissions from crop insurance and likely benefits from other risk sharing instruments (Table 6.20). <u>Adaptation</u>: Moderate benefits by buffering and transferring weather risk, saving farmers the cost of crop losses. However, overly subsidised insurance can undermine the market's role in pricing risks and thus depress more rapid adaptation strategies (Table 6.28; Meze-Hausken et al. 2009; Skees and Collier 2012; Jaworski 2016). <u>Desertification</u>: The impacts of risk sharing globally have not been quantified (Table 6.36). <u>Land degradation</u>: Variable impacts as evidence suggests that subsidised insurance in particular can increase crop production in marginal lands, and reforming this would lead to benefits (Table 6.44). <u>Food security</u>: Small to moderate benefits for food security, as risk sharing often promotes food supply sharing (Table 6.52).</p>

1 Note: Cell colours correspond to the large, moderate and small categories shown in Table 6.53. Dark blue = large positive; mid-blue = moderate positive; light blue = small
2 positive; no colour = no effect; light red = small negative; mid-red = moderate negative; dark red = large negative; green = variable; ND = no data.

3

1 **6.4 Managing interactions and interlinkages**

2 Having assessed the potential of each response option for contributing to addressing mitigation,
3 adaptation, desertification, land degradation and food security in section 6.3, this section assesses the
4 feasibility of each response option with respect to cost, barriers, and issues of saturation and
5 reversibility (6.4.1), before assessing the sensitivity of the response options to future climate change
6 (6.4.2) and examining the contribution of each response option to ecosystem services (classified
7 according to Nature's Contribution to People (IPBES 2018) and to sustainable development (assessed
8 against the UN Sustainable Development Goals) (6.4.3). Section 6.4.4 examines opportunities for
9 implementation of integrated response options, paving the way to potential policies examined in
10 Chapter 7, before the consequences of delayed action are assessed in section 6.4.5.

11 **6.4.1 Feasibility of the integrated response options with respect to costs, barriers,** 12 **saturation and reversibility**

13 For each of the response options, Tables 6.62-6.69 summarise the feasibility with respect to saturation
14 and reversibility and cost, technological, institutional, socio-cultural and environmental and
15 geophysical barriers (the same barrier categories used in SR15).

16 Many land management options face issues of saturation and reversibility; however, these are not of
17 concern for the value chain and risk management options. Reversibility is an issue for all options that
18 increase terrestrial carbon stock, either through increased soil carbon or changes in land cover (e.g.,
19 reforestation, afforestation), since future changes in climate or land cover could result in reduced
20 carbon storage (Smith 2013). In addition, the benefits of options that improve land management (e.g.,
21 improved cropland management, improved grazing management) will cease if the practice is halted,
22 reversing any potential benefits.

23 The cost of the response options varies substantially, with some options having relatively low cost
24 (e.g., the cost of agroforestry is less than USD 10 tCO₂e⁻¹) while others have much higher costs (e.g.,
25 the cost of BECCS could be as much as USD 250 tCO₂e⁻¹). In addition to cost, other economic
26 barriers may prevent implementation; for example, agroforestry is a low- cost option (Smith et al.
27 2014a), but lack of reliable financial support could be a barrier (Hernandez-Morcillo et al. 2018).
28 Additionally, there are a number of reasons why even no cost options are not adopted, including risk
29 aversion, lack of information, market structure, externalities, and policies (Jaffe 2019).

30 Some of the response options have technological barriers that may limit their wide-scale application
31 in the near-term. For example, BECCS has only been implemented at small-scale demonstration
32 facilities (Kemper 2015a); challenges exist with upscaling these options to the levels discussed in this
33 Chapter.

34 Many response options have institutional and socio-cultural barriers. Institutional barriers include
35 governance, financial incentives and financial resources. For example, management of supply chains
36 faces challenges related to political will within trade regimes, economic laissez-faire policies that
37 discourage interventions in markets, and the difficulties of coordination across economic sectors
38 (Poulton et al. 2006; Cohen et al. 2009; Gilbert 2012a). Implementation of other options, e.g.,
39 BECCS, is limited by the absence of financial incentives.

40 Options like dietary change face socio-cultural barriers; while diets have changed in the past, they are
41 deeply culturally embedded and behaviour change is extremely difficult to effect, even when health
42 benefits are well known (Macdiarmid et al. 2018). For some options, the specific barrier is dependent
43 on the region. For example, barriers to reducing food waste in industrialised countries include
44 inconvenience, lack of financial incentives, lack of public awareness, and low prioritisation (Kummu
45 et al. 2012; Graham-Rowe et al. 2014). Barriers in developing countries include reliability of

- 1 transportation networks, market reliability, education, technology, capacity, and infrastructure
- 2 (Kummu et al. 2012).

1

2

3

Table 6.62 Feasibility of land management response options in agriculture, considering cost, technological, institutional, socio-cultural and environmental and geophysical barriers and saturation and reversibility. See also supplementary material.

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical	Context and sources
Increased food productivity								<u>Biophysical</u> : only if limited by climatic and environmental factors. <u>Sources</u> : Barnes and Thomson 2014; Martin et al. 2015; Olesen and Bindi 2002; Pretty and Bharucha 2014; Schut et al. 2016
Improved cropland management								<u>Institutional</u> : only in some regions (e.g., poor sustainability frameworks). <u>Sources</u> : Bryan et al. 2009b; Bustamante et al. 2014b; Madlener et al. 2006; Reichardt et al. 2009; Roesch-McNally et al. 2017; Singh and Verma 2007; Smith et al. 2008, 2014a
Improved grazing land management								<u>Institutional</u> : only in some regions (e.g., need for extension services). <u>Sources</u> : Herrero et al. 2016; Singh and Verma 2007; Smith et al. 2008, 2015; McKinsey & Co., 2011; Ndoro et al., 2014;
Improved livestock management								<u>Economic</u> : improved productivity is cost negative, but others (e.g. dietary additives) are expensive. <u>Institutional</u> : only in some regions (e.g. need for extension services). <u>Sources</u> : Herrero et al. 2016; McKinsey and Company 2009; Rojas-Downing et al. 2017b; Smith et al. 2008; Thornton et al. 2009; Beauchemin et al., 2008; Ndoro et al., 2014;
Agroforestry								<u>Economic</u> : low cost but may lack reliable financial support. <u>Institutional</u> : only in some regions (e.g., seed availability). <u>Sources</u> : Lillesø et al. 2011; Meijer et al. 2015; Sileshi et al. 2008; Smith et al. 2007, 2014a
Agricultural diversification								More support from extension services, access to inputs and markets, economic incentives for producing a certain crop or livestock product, research and investments focused on adapted varieties and climatic resilient systems, a combination of agricultural and non-agricultural activities (e.g., off farm jobs) are all important interventions aimed at overcoming barriers to agricultural diversification. <u>Sources</u> : Ahmed and Stepp 2016b; Barnes et al. 2015; Barnett and Palutikof 2015; Martin and Lorenzen 2016; Roesch-McNally et al. 2016; Waha et al. 2018
Reduced grassland conversion to cropland								<u>Economics</u> : Avoiding conversion is low cost, but there may be significant opportunity costs associated with foregone production of crops. <u>Institutional</u> : only in some regions (e.g., poor governance to prevent conversion)
Integrated water								<u>Institutional</u> : effective implementation is dependent on the adoption of a combination of 'hard',

management								infrastructural, and ‘soft’ institutional measures. <u>Socio-cultural</u> : Education can be a barrier and some strategies (e.g. site-specific water management, drip irrigation) can be expensive. Cultural / behavioural barriers are likely to be small. <u>Sources</u> : Dresner et al. 2015; Erwin 2009; Lotze et al. 2006; Thornton et al. 2009
------------	--	--	--	--	--	--	--	---

1 Note: For saturation and reversibility, a blue cell indicates that these issues are not important, and a red cell indicates that saturation and reversibility are concerns. For the
 2 cost column, a blue cell indicates low cost (< USD10 tCO₂e⁻¹ or < USD20 ha⁻¹), a yellow cell indicates medium cost (USD10-USD100 tCO₂e⁻¹ or USD20-USD100 ha⁻¹), and
 3 a red cell indicates high cost (>USD100 tCO₂e⁻¹ or USD200 ha⁻¹). The cost thresholds in USD tCO₂e⁻¹ are from Griscom et al. (2017a); thresholds in USD ha⁻¹ are chosen to
 4 be comparable, but precise conversions will depend on the response option. For the technological, institutional, socio-cultural and environmental and geophysical barriers,
 5 dark blue indicates high current feasibility (no barriers), mid-blue indicates medium current feasibility (moderate barriers) and light blue indicates low current feasibility
 6 (large barriers). Green represents variable barriers.

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical	Context and sources
Improved forest management								Sources: Seidl et al. 2014
Reduced deforestation and degradation								<u>Economic</u> : requires transaction and administration costs <u>Sources</u> : Kindermann et al. 2008; Overmars et al. 2014; Busch and Engelmann 2017;
Reforestation and forest restoration								<u>Sources</u> : Strengers et al. 2008
Afforestation								<u>Sources</u> : Idris Medugu et al. 2010a; Kreidenweis et al. 2016b

7 **Table 6.63 Feasibility of land management response options in forests, considering cost, technological, institutional, socio-cultural and environmental and**
 8 **geophysical barriers and saturation and reversibility. See also supplementary material.**

3 **and geophysical barriers and saturation and reversibility. See also supplementary material.**

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical	Context and sources
Fire management								<u>Economic</u> : the cost of its implementation is moderate, since it requires constant maintenance, and can be excessive for some local communities. <u>Sources</u> : Freeman et al. 2017; Hurteau et al. 2014; North et al. 2015
Reduced landslides and								<u>Sources</u> : Gill and Malamud 2017; Maes et al. 2017; Noble et al. 2014

natural hazards								
Reduced pollution including acidification								Sources: Begum et al., 2011; Shah et al., 2018; Yamineva & Romppanen, 2017; WMO 2015
Management of invasive species / encroachment								<u>Technological</u> : in the case of natural enemies. <u>Socio-cultural</u> : Education can be a barrier, where populations are unaware of the damage caused by the invasive species, but cultural / behavioural barriers are likely to be small. <u>Institutional</u> : where agricultural extension and advice services are poorly developed. <u>Source</u> : Dresner et al. 2015
Restoration and reduced conversion of coastal wetlands								<u>Economic</u> : can be cost-effective at scale. <u>Institutional</u> : only in some regions (e.g., poor governance of wetland use). <u>Socio-cultural</u> : educational barriers (e.g., lack of knowledge of impact of wetland conversion), though cultural / behavioural barriers are likely to be small. <u>Sources</u> : Erwin 2009; Lotze et al. 2006
Restoration and reduced conversion of peatlands								<u>Institutional</u> : only in some regions (e.g., lack of inputs). <u>Sources</u> : Bonn et al. 2014; Worrall et al. 2009
Biodiversity conservation								<u>Economic</u> : While protected areas and other forms of biodiversity conservation can be cost-effective, they are often underfunded relative to needs. <u>Institutional</u> : There have been challenges in getting systematic conservation planning to happen, due to institutional fragmentation and overlapping mandates. <u>Socio-cultural</u> : Despite the fact that biodiversity conservation may provide co-benefits like water or carbon protection, local populations often have had social and cultural conflicts with protected areas and other forms of exclusionary biodiversity conservation that are imposed in a top-down fashion or which restrict livelihood options. <u>Sources</u> : Emerton et al. 2006; Hill et al. 2015; Langford et al. 2011; Larsen et al. 2012; Schleicher 2018; Wei et al. 2018; Wilkie et al. 2001

 3 **barriers and saturation and reversibility. See also supplementary material.**

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical	Context and sources
Management of urban sprawl								There are economic and political forces that benefit from less-regulated urban development. <u>Sources</u> : Tan et al. 2009

Livelihood diversification	Blue	Blue	White	White	White	Light Blue	White	<u>Economic</u> : Expanded diversification can cost additional financial resources. <u>Socio-cultural</u> : problems with adoption of new or unfamiliar crops and livelihoods. <u>Sources</u> : Ahmed and Stepp 2016b; Berman et al. 2012; Ngigi et al. 2017
Use of local seeds	Blue	Blue	White	Dark Blue	Light Blue	Blue	White	<u>Economic</u> : Local seeds are highly cost effective, and do not require new technology. <u>Institutional</u> : barriers from agronomy departments and businesses promoting commercial seeds. <u>Socio-cultural</u> : preferences for some non-local seed sourced crops. <u>Sources</u> : Reisman 2017; Timmermann and Robaey 2016
Disaster risk management	Blue	Blue	White	White	Light Blue	White	White	<u>Economic</u> : DRM systems can be initially costly, but usually pay for themselves over time. <u>Institutional</u> : some barriers in terms of getting initial support and will behind new systems. <u>Sources</u> : Birkmann et al. 2015b; Hallegatte 2012
Risk sharing instruments	Blue	Blue	Yellow	White	White	Blue	White	There are few barriers to risk sharing instruments, as they are often low cost and low technology. <u>Socio-cultural</u> : some barriers to instruments like crop insurance, which some farmers in developing countries are not familiar with. <u>Sources</u> : Goodwin and Smith 2013

1 Note: See footnotes for Table 6.62.

2

1

2 **6.4.2 Sensitivity of the Integrated Response Options to climate change impacts**

3 With continued increases in warming, there are risks to the efficacy of some of the response options due
4 to future climate change impacts, such as increased climate variability and extreme events. While many of
5 the response options can help increase capacity to deliver adaptation benefits (section 6.3.2), beyond
6 certain thresholds of climate impacts they may be less effective or increasingly risky options. This
7 requires that some response options need to anticipate these climate impacts in their implementation. We
8 outline some of these impacts below.

9 *Agriculture response options:* Increased food productivity as a response option is highly sensitive to
10 climate change impacts. Chapter 5 (section 5.2.3.1) notes that global mean yields of some crops (maize
11 and soybean) decrease with warming, while others (rice and wheat) increase with warming, up to a
12 threshold of 3°C. Similarly, improved cropland management response options that rely on crop
13 diversification or improved varieties may face challenges in efficacy from production declines. Improved
14 grazing land management may continue to be feasible as a response option in the future under climate
15 change in northern regions but will likely become more difficult in tropical regions and Australia as
16 temperature rises will reduce the carrying capacity of lands (section 5.2.3.2; Nardone et al. 2010).
17 Improved livestock management also faces numerous challenges, particularly related to stresses on
18 animals from temperatures, water, and diseases; overall, livestock numbers are projected to decline 7.5–
19 9.6% by 2050 (section 5.2.3.2; Rivera-Ferre et al. 2016; Boone et al. 2018). Pastoralists may also be less
20 likely to implement improved measures due to other risks and vulnerabilities under climate change
21 (Thornton et al. 2009a).

22 The impact of climate change on agroforestry is more difficult to model than single crops in process-
23 based crop models, as agroforestry systems are far more complex (Luedeling et al. 2014); thus, it is
24 unknown how the efficacy of this response option might be impacted. Agricultural diversification has
25 been promoted as an adaptive strategy to climate impacts, given that diversity is known to increase
26 resiliency of agricultural and natural systems, such as in resistance to increased pests or diseases; it also
27 can provide diversified income portfolios when some crops may become sensitive to climate events
28 (Bradshaw et al. 2004; Lin 2011). Diversified farms are expected to increase in Africa by 2060 as
29 specialised farms with single crops face challenges under climate change (Seo 2010). However, it is not
30 known if these options and advantages of diversification have a temperature threshold beyond which they
31 are less effective.

32 Reduced grassland conversion is not likely to be affected as a response option *per se* since it is directed at
33 conserving natural grassland areas, but these areas may face increased pressures for conversion if farmers
34 experience crop failures under climate change and need to extensify holdings to make up for losses.
35 Lobell et al. (2013) have estimated the impacts of investment decisions to adapt to the effects of climate
36 change on crop yields to 2050 and find that cropland will expand over 23% more land area (over
37 3 Mkm²), mostly in Latin America and Sub-Saharan Africa.

38 Integrated water management to improve water availability and reliability of water for agricultural
39 production is likely to become more challenging in future scenarios of water declines, which are likely to
40 be regionally uneven (section 2.5, 6.4.4).

41 *Forest response options:* The availability of improved forest management as a response option can be
42 impacted by climate-induced changes, including increased diseases, pests and fires (Section 4.5.1.2; Dale
43 et al. 2001; Logan et al. 2003). These impacts will affect reforestation and afforestation response options

1 as well. Locatelli et al. (2015d) note that climate changes will influence seedling establishment, tree
2 growth and mortality, and the presence of invasive species and/or pests; these can be buffered with
3 modified silvicultural practices including species selection (Pawson et al. 2013). Climate changes can also
4 alter the sink capacity for vegetation carbon sequestration, reducing the potential for REDD, reforestation
5 and afforestation (Bonan 2008b; Mahli et al. 2002).

6 *Soil management:* Climate changes can alter the sink capacity for soil carbon sequestration, reducing the
7 potential for increased soil organic carbon as an option. Projected climate changes can reduce soil
8 resilience to extreme weather, pests and biological invasion, environmental pollutants and other pressures,
9 making reduced soil erosion and reduced soil compaction as response options harder to achieve (Smith et
10 al. 2015). Climate change will likely increase demand for irrigation in dryland areas, which can increase
11 risks of salinisation, diminishing the effectiveness of this response (Smith et al. 2015). Biochar additions
12 to soil may be affected by future climatic changes, such as rising soil temperatures, but little is known
13 given that most research on the subject is from laboratory and not *in situ* field experiments, and there are
14 wide estimates of the stability and residence times of biochar from this literature (Gurwick et al. 2013).

15 *Other ecosystem management:* Fire management is likely to become more challenging in a changing
16 climate; some studies suggest an 50% increase in fire occurrence by end of the century in circumboreal
17 forests (Flannigan et al. 2009). Landslide risks are related to climate through total rainfall, rainfall
18 intensity, air temperature and the general weather system (Gariano and Guzzetti 2016a); thus reduced
19 landslides and natural hazards as a response option will be made more difficult by increasing storms and
20 seasonality of rainfall events projected for many areas of the world. Reduced pollution is likely less
21 affected by climate change and can continue to be an option despite increasing temperatures.

22 Conversely, some invasive species may thrive under climate change, such as moving to new areas or
23 being less susceptible to control protocols (Hellmann et al. 2008). Conversion of coastal wetlands will be
24 more difficult to halt if loss of productive land elsewhere encourages development on these lands, but
25 coastal wetlands will likely adapt to increased CO₂ and higher sea levels through sediment accretion,
26 which will also enhance their capacity to act as carbon sinks (Duarte et al. 2013). While subarctic
27 peatlands are at risk due to warming, these are not the main peatlands that are at risk from agricultural
28 conversion (Tarnocai 2006); these peatlands, such as those in the tropics, may be more vulnerable in
29 hotter scenarios to water table alterations and fire risk (Gorham 1991). Biodiversity conservation, such as
30 through protected areas or corridors, may be threatened by increased land expansion under agriculture in
31 climate change scenarios, including the newly available land in northern climates that may become
32 agriculturally suited (Gimona et al. 2012), lessening the effectiveness of this response option.

33 *CDR:* The efficacy of enhanced weathering is not likely to be affected by future climate changes. On the
34 other hand, climate change will affect the productivity of bioenergy crops (Cronin et al. 2018),
35 influencing the mitigation potential of bioenergy and BECCS (Calvin et al. 2013a; Kyle et al. 2014).
36 There is uncertainty in the sign and magnitude of the effect of climate change on bioenergy crop yields.
37 As a result, there is uncertainty in whether climate change will increase or decrease the potential of
38 bioenergy and BECCS.

39 *Demand management of value chains:* For most response options in demand side management, the tools
40 are generally not made more difficult by future climate changes. For example, dietary change is not likely
41 to be affected by climate change, and in fact, the opposite is more likely; that diets will shift in response
42 to climate change impacts as reflected in high prices for some staple grains and meats, the productivity of
43 which may be reduced (Tigchelaar et al. 2018). However, there is some indication that fruit and vegetable
44 production will also be reduced in future scenarios, making healthier diets potentially harder to achieve in

1 some regions (Springmann et al. 2016). Reduced post-harvest losses and reduced food waste may become
2 an even more important option if water or heat stresses under climate change reduce overall harvests.
3 Material substitution does have risks related to the availability of products if there are declines in the
4 growth of forest and other biomass in certain future scenarios over time, although some evidence
5 indicates that biomass may increase in the short-term with limited warming (Boisvenue and Running
6 2006).

7 *Supply management of value chains:* Sustainable sourcing relies on being able to produce consumer
8 goods sustainably (palm oil, timber, cocoa, etc), and these may be at risk; for example, areas suitable for
9 oil palm production are estimated to decrease by 75% by 2100 (Paterson et al. 2017). Improved
10 management of supply chains is likely to increase in importance as a tool to manage food security, given
11 that climate change threatens to lead to more production shocks in the future (Baldos and Hertel 2015).
12 For enhanced urban food systems, climate stresses like heat island effects or increased water scarcity in
13 urban areas may reduce the viability of food production in certain urban systems (da Silva et al. 2012).
14 Improved food processing and retailing and improved energy use in agriculture are not likely to be
15 impacted by climate change.

16 *Risk management options:* Most risk management response options are not affected by climate impacts
17 *per se*, although the increased risks that people may face will increase the need for funding and support to
18 deploy these options. For example, disaster risk management will likely increase in importance in helping
19 people adapt to longer-term climate changes (Begum et al. 2014); it is also likely to cost more as
20 increased impacts of climate change, such as intensification or frequency of storm events may increase.
21 Management of urban sprawl may also be challenged by increased migration driven by climate change, as
22 people displaced by climate change may move to unregulated urban areas (Adamo 2010). Livelihood
23 diversification can assist in adapting to climate changes and is not likely to be constrained as a response
24 option, as climate-sensitive livelihoods may be replaced by others less so. Use of local seeds as an
25 effective response options may depend on the specific types of seeds and crops used, as some may not be
26 good choices under increased heat and water stress (Gross et al. 2017). Risk sharing instruments are
27 unlikely to be affected by climate change, with the exception of index and crop insurance, which may
28 become unaffordable if too many climate shocks result in insurance claims decreasing the ability of the
29 industry to provide this tool (Mills 2005).

30

31

32 **Cross-Chapter Box 8: Ecosystem services and Nature's Contributions to** 33 **People, and their relation to the land-climate system**

34 Pamela McElwee (The United States of America), Jagdish Krishnaswamy (India), Lindsay Stringer
35 (United Kingdom)

36 This Cross-Chapter Box describes the concepts of *ecosystem services (ES)* and *nature's contributions to*
37 *people (NCP)*, and their importance to climate-land interactions. ES have become a useful concept to
38 describe the benefits that humans obtain from ecosystems and have strong relevance to sustainable land
39 management (SLM) decisions and their outcomes, while NCP is a new approach championed by the
40 Intergovernmental Panel on Biodiversity and Ecosystem Services (IPBES) (explained below). It is timely
41 that this SRCCL report includes attention to ES/NCP, as the previous Special Report on Land-Use, Land-
42 Use Change and Forestry (LULUCF) did not make use of these concepts and focused mostly on carbon

1 fluxes in land-climate interactions (IPCC 2000). The broader mandate of SRCCL is to address not just
2 climate but land degradation, desertification and food security issues, all of which are closely linked to the
3 provisioning of various ES/NCP, and the Decision and Outline for SRCCL explicitly requests an
4 examination of how desertification and degradation “impacts on ecosystem services (e.g. water, soil and
5 soil carbon and biodiversity that underpins them)”. Attention to ES/NCP is particularly important in
6 discussing co-benefits, trade-offs and adverse side effects of potential climate change mitigation, land
7 management, or food security response options, as many actions may have positive impacts on climate
8 mitigation or food production but may also come with a decline in ES provisioning, or adversely impact
9 biodiversity {see 6.4.3}. This box considers the importance of the ES/NCP concepts, how definitions
10 have changed over time, continuing debates over operationalisation and use of these ideas, and finally
11 concludes with how ES/NCP are treated in various chapters in this report.

12 While the first uses of the term “ecosystem services” appeared in the 1980s (Lele et al. 2013; Mooney and
13 Ehrlich 1997), the roots of interest in ES extends back to the late 1960s and the extinction crisis, with
14 concern that species decline might cause loss of valuable benefits to humankind (King 1966; Helliwell
15 1969; Westman 1977). While concern over extinction was explicitly linked to biodiversity loss, later ideas
16 beyond biodiversity have animated interest in ES, including the multi-functional nature of ecosystems. A
17 seminal paper by Costanza et al. (1997) attempted to put an economic value on the stocks of global ES
18 and natural capital on which humanity relied. Attention to ES expanded rapidly after the Millennium
19 Ecosystem Assessment (Millenium Ecosystem Assessment (MA) 2005), and the linkages between ES and
20 economic valuation of these functions were addressed by the Economics of Ecosystems and Biodiversity
21 study (TEEB 2009). The ES approach has increasingly been used in global and national environmental
22 assessments, including the United Kingdom National Ecosystem Assessment (Watson et al. 2011), and
23 recent and ongoing regional and global assessments organised by the Intergovernmental Science-Policy
24 Platform on Biodiversity and Ecosystem Services (IPBES) (Díaz et al. 2015). IPBES has recently
25 completed an assessment on land degradation and restoration that addresses a range of ES issues of
26 relevance to the SRCCL report (IPBES 2018).

27 The MA defined ES as “the benefits that ecosystems provide to people,” and identified four broad
28 groupings of ES: *provisioning services* such as food, water, or timber; *regulating services* that have
29 impacts on climate, diseases or water quality, among others; *cultural services* that provide recreational,
30 aesthetic, and spiritual benefits; and *supporting services* such as soil formation, photosynthesis, and
31 nutrient cycling (Millenium Ecosystem Assessment (MA) 2005). The MA emphasised that people are
32 components of ecosystems engaged in dynamic interactions, and particularly assessed how changes in ES
33 might impact human well-being, such as access to basic materials for living (shelter, clothing, energy);
34 health (clean air and water); social relations (including community cohesion); security (freedom from
35 natural disasters); and freedom of choice (the opportunity to achieve) (Millenium Ecosystem Assessment
36 (MA) 2005). Upon publication of the MA, incorporation of ES into land use change assessments
37 increased dramatically, including studies on how to maximise provisioning of ES alongside human well-
38 being (Carpenter et al. 2009); how intensive food production to feed growing populations required trading
39 off a number of important ES (Foley et al. 2005); and how including ES in GCMs indicated increasing
40 vulnerability to ES change or loss in future climate scenarios (Schröter et al. 2005).

41 Starting in 2015, IPBES has introduced a new related concept to ES, that of *nature’s contributions to*
42 *people (NCP)*, which are defined as “all the contributions, both positive and negative, of living nature
43 (i.e., diversity of organisms, ecosystems and their associated ecological and evolutionary processes) to the
44 quality of life of people” (Díaz et al. 2018). NCP are divided into regulating NCP, non-material NCP, and
45 material NCP, a different approach than used by the MA (see figure 1). However, IPBES has stressed

NCP are a particular way to think of ES, rather than a replacement for ES. Rather, the concept of NCP is proposed to be broader umbrella to engage a wider range of scholarship, particularly from the social sciences and humanities, and a wider range of values, from intrinsic to instrumental to relational, particularly those held by indigenous and other peoples (Redford and Adams 2009; Schröter et al. 2014; Pascual et al. 2017; Díaz et al. 2018). The differences between the MA and IPBES approaches can be seen in Table 1.

Table 1. Comparison of MA and IPBES categories and types of ES and NCP

MA category	MA: Ecosystem Services	IPBES category	IPBES: Nature's Contributions to People
Supporting services	Soil formation		
	Nutrient cycling		
	Primary production		
Regulating services		Regulating Contributions	Habitat creation and maintenance
	Pollination		Pollination and dispersal of seeds and other propagules
	Air quality regulation		Regulation of air quality
	Climate regulation		Regulation of climate
	Water regulation		Regulation of ocean acidification
	See above		Regulation of freshwater quantity, flow and timing
	Water purification and waste treatment		Regulation of freshwater and coastal water quality
	Erosion regulation		Formation, protection and decontamination of soils and sediments
	Natural hazard regulation		Regulation of hazards and extreme events
	Pest regulation and disease regulation		Regulation of organisms detrimental to humans
Provisioning Services	Fresh water	Material Contributions	Energy
	Food		Food and feed
	Fibre		Materials and assistance

	Medicinal and biochemical and genetic		Medicinal, biochemical and genetic resources
Cultural Services	Aesthetic values	Nonmaterial Contributions	Learning and inspiration
	Recreation and ecotourism		Physical and psychological experiences
	Spiritual and religious values		Supporting identities
			Maintenance of options

1 Sources: Millenium Ecosystem Assessment (MA) 2005; Díaz et al. 2018

2 While there are many similarities between ES and NCP as seen above, the IPBES decision to use the NCP
3 concept has been controversial, with some people arguing that an additional term is superfluous, that it
4 incorrectly associates ES with economic valuation, and that the NCP concept is not useful for policy
5 uptake (Braat 2018; Peterson et al. 2018). Others have argued that the MA approach is outdated, did not
6 explicitly address biodiversity, and confused different concepts, like economic goods, ecosystem
7 functions, and general benefits (Boyd and Banzhaf 2007). Moreover, for both ES and NCP approaches, it
8 has been difficult to make complex ecological processes and functions amenable to assessments that can
9 be used and compared across wider landscapes, different policy actors, and multiple stakeholders (de
10 Groot et al. 2002; Naem et al. 2015; Seppelt et al. 2011). There remain competing categorisation
11 schemes for ES, as well as competing metrics on how most ES might be measured (Wallace 2007;
12 Potschin and Haines-Young 2011; Danley and Widmark 2016; Nahlik et al. 2012). The implications of
13 these discussions for this SRCCL report is that there remain many areas of uncertainty with regard to
14 much ES/NCP measurement and valuation, which will have ramifications for choosing response options
15 and policies.

16 This report addresses ES/NCP in multiple ways. Individual chapters have used the term ES in most cases,
17 especially since the preponderance of existing literature uses the ES terminology. For example, Chapter 2
18 discusses CO₂ fluxes, nutrients, and water budgets as important ES deriving from land-climate
19 interactions. Chapters 3 and 4 discuss issues such as biomass production, soil erosion, biodiversity loss,
20 and other ES affected by land use change. Chapter 5 discusses both ES and NCP issues surrounding food
21 system provisioning and trade-offs.

22 In chapter 6, the concept of NCP is used. For example, in chapter 6 Tables 6.70 to 6.72, possible response
23 options to respond to climate change, to address land degradation or desertification, and to ensure food
24 security are cross-referenced against the 18 NCP identified by Díaz et al. (2018) to see where there are
25 co-benefits and adverse side-effects. For instance, while BECCS may deliver on climate mitigation, it
26 results in a number of adverse side-effects that are significant with regard to water provisioning, food and
27 feed availability, and loss of supporting identities if BECCS competes against local land uses of cultural
28 importance. Chapter 7 has an explicit section 7.2.2.2 that covers risks due to loss of biodiversity and ES
29 and Table 7.1 that includes policy responses to various land-climate-society hazards, some of which are
30 likely to enhance risk of loss of biodiversity and ES. A case-study on the impact of renewable energy on
31 biodiversity and ES is also included. Chapter 7 also notes that because there is no SDG covering fresh-

1 water biodiversity and aquatic ecosystems; this policy gap may have adverse consequences for the future
2 of rivers and associated ES.

4 **6.4.3 Impacts of integrated response options on Nature’s Contributions to People and the** 5 **UN Sustainable Development Goals**

6 In addition to evaluating the importance of our response options for climate mitigation, adaptation, land
7 degradation, desertification and food security, it is also necessary to pay attention to other co-benefits and
8 trade-offs that may be associated with these responses. How the different options impact progress toward
9 the SDG can be a useful shorthand for looking at the social impacts of these response options. Similarly,
10 looking at how these response options increase or decrease the supply of ecosystem services/NCP (see
11 Cross-Chapter Box 8 on Ecosystem Services in this chapter) can be a useful shorthand for a more
12 comprehensive environmental impact beyond climate and land. Such evaluations are important as
13 response option may lead to unexpected trade-offs with social goals (or potential co-benefits) and impacts
14 on important environmental indicators like water or biodiversity. Similarly, there may be important
15 synergies and co-benefits associated with some response options that may increase their cost-
16 effectiveness or attractiveness. As we note in section 6.4.4, many of these synergies are not automatic,
17 and are dependent on well-implemented and coordinated activities in appropriate environmental contexts
18 (6.4.4.1), often requiring institutional and enabling conditions for success and participation of multiple
19 stakeholders (6.4.4.3).

20 In the following sections and tables, we evaluate each response option against 17 SDG and 18 NCP.
21 Some of the SDG categories appear similar to each other, such as SDG 13 on “climate action” and an
22 NCP titled “climate regulation”. However, SDG 13 includes targets for both mitigation and adaptation, so
23 options were weighed by whether they were useful for one or both. On the other hand, the NCP
24 “regulation of climate” does not include an adaptation component, and refers to specifically to “positive
25 or negative effects on emissions of greenhouse gases and positive or negative effects on biophysical
26 feedbacks from vegetation cover to atmosphere, such as those involving albedo, surface roughness, long-
27 wave radiation, evapotranspiration (including moisture-recycling) and cloud formation or direct and
28 indirect processes involving biogenic volatile organic compounds (BVOC), and regulation of aerosols and
29 aerosol precursors by terrestrial plants and phytoplankton” (Díaz et al. 2018).

30 In all tables, colours represent the direction of impact: positive (blue) or negative (brown), and the scale
31 of the impact (dark colours for large impact and/or strong evidence to light colours for small impact
32 and/or less certain evidence). Supplementary tables show the values and references used to define the
33 colour coding used in all tables. In cases where there is no evidence of an interaction or at least no
34 literature on such interactions, the cell is left blank. In cases where there are both positive and negative
35 interactions and the literature is uncertain about the overall impact, a note appears in the box. In all cases,
36 many of these interactions are contextual, or the literature only refers to certain co-benefits in specific
37 regions or ecosystems, so readers are urged to consult the supplementary tables for the specific caveats
38 that may apply.

39 **6.4.3.1 Impacts of integrated response options on Nature’s Contributions to People**

40 Tables 6.70–6.72 summarise the impacts of the response options on NCP supply. Examples of synergies
41 between response options and NCP include positive impacts on habitat maintenance (NCP 1) from
42 activities like invasive species management and agricultural diversification. For the evaluation process,
43 we considered that NCP are about ecosystems, therefore options which may have overall positive effects,

1 but which are *not* ecosystem-based are not included; for example, improved food transport and
2 distribution could reduce ground-level ozone and thus improve air quality, but this is not an ecosystem-
3 based NCP. Similarly, energy efficiency measures would increase energy availability, but the ‘energy’
4 NCP refers specifically to biomass-based fuel provisioning. This necessarily means that the land
5 management options have more direct NCP effects than the value chain or governance options, which are
6 less ecosystem-focused.

7 In evaluating NCP, we have also tried to avoid ‘indirect’ effects – that is a response option might increase
8 household income which then could be invested in habitat-saving actions, or dietary change would lead to
9 conservation of natural areas, which would then led to increased water quality. Similarly, material
10 substitution would increase wood demand, which in turn might lead to deforestation which might have
11 water regulation effects. These can all be considered *indirect* impacts on NCP, which were not evaluated⁷.
12 Instead, the assessment focuses as much as possible on *direct* effects only: for example, local seeds
13 policies preserve local landraces, which *directly* contribute to ‘maintenance of genetic options’ for the
14 future. Therefore, this NCP table is a conservative estimation of NCP effects; there are likely many more
15 secondary effects, but they are too difficult to assess, or the literature is not yet complete or conclusive.

16 Further, many NCP trade-off with one another (Rodriguez et al 2006), so supply of one might lead to less
17 availability of another – for example, use of ecosystems to produce bioenergy will likely lead to decreases
18 in water availability if mono-cropped high intensity plantations are used (Gasparaos et al 2011).

19 Overall, several response options stand out as having co-benefits across 10 or more NCP with no adverse
20 impacts: improved cropland management, agroforestry, forest management and forest restoration,
21 increased soil organic content, fire management, restoration and avoided conversion of coastal wetlands,
22 and use of local seeds. Other response options may have strengths in some NCP but require trade-offs
23 with others. For example, reforestation and afforestation bring many positive benefits for climate and
24 water quality but may trade-off with food production (Table 6.70). Several response options, including
25 increased food productivity, bioenergy and BECCS, and some risk sharing instruments like crop
26 insurance, have significant negative consequences across multiple NCP.

⁷ FOOTNOTE: The exception is NCP 6, regulation of ocean acidification, which is by itself an indirect impact. Any option that sequesters CO₂ would lower the atmospheric CO₂ concentration, which then indirectly increases the seawater pH. Therefore, any action that directly increases the amount of sequestered carbon is noted in this column, but not any action that avoids land use change and therefore indirectly avoids CO₂ emissions.

Table 6.70 Impacts on Nature’s Contributions to People of integrated response options based on land management

<u>Integrated response options based on land management</u>	Habitat creation and maintenance	Pollination and dispersal of seeds and other propagules	Regulation of air quality	Regulation of climate	Regulation of ocean acidification	Regulation of freshwater quantity, flow and timing	Regulation of freshwater and coastal water quality	Formation, protection and decontamination of soils and sediments	Regulation of hazards and extreme events	Regulation of organisms detrimental to humans	Energy	Food and feed	Materials and assistance	Medicinal, biochemical and genetic resources	Learning and inspiration	Physical and psychological experiences	Supporting identities	Maintenance of options
Increased food productivity

6.4.3.2 *Impacts of integrated response options on the UN Sustainable Development Goals*

Tables 6.73–6.75 summarise the impact of the integrated response options on the UN SDG. Some of the synergies between response options and SDG in the literature include positive poverty reduction impacts (SDG 1) from activities like improved water management or improved management of supply chains, or positive gender impacts (SDG 5) from livelihood diversification or use of local seeds. Because many land management options only produce indirect or unclear effects on SDG, we did not include these where there was no literature. Therefore, the value chain and governance options appear to offer more direct benefits for SDG.

However, it is noted that some SDG are internally difficult to assess because they contain many targets, not all of which could be evaluated (e.g., SDG 17 is about partnerships, but has targets ranging from foreign aid to debt restructuring to technology transfer to trade openness). Additionally, it is noted that some SDG contradict one another – for example, SDG 9 to increase industrialisation and infrastructure and SDG 15 to improve life on land. More industrialisation is likely to lead to increased resource demands with negative effects on habitats. Therefore, a positive association on one SDG measure might be directly correlated with a negative measure on another, and the table needs to be read with caution for that reason. The specific caveats on each of these interactions can be found in the supplementary material tables in the Chapter 6 appendix.

Overall, several response options have co-benefits across 10 or more SDG with no adverse side effects on any SDG: increased food production, improved grazing land management, agroforestry, integrated water management, reduced post-harvest losses, sustainable sourcing, livelihood diversification and disaster risk management. Other response options may have strengths in some SDG but require trade-offs with others. For example, use of local seeds bring many positive benefits for poverty and hunger reduction, but may reduce international trade (SDG 17). Other response options like enhanced urban food systems, management of urban sprawl, or management of supply chains are generally positive for many SDG but may trade-off with one, like clean water (SDG 6) or decent work (SDG 8), as they may increase water use or slow economic growth. Several response options, including avoidance of grassland conversion, reduced deforestation and degradation, reforestation and afforestation, biochar, restoration and avoided conversion of peatlands and coastlands, have trade-offs across multiple SDG, primarily as they prioritise land health over food production and poverty reduction. Several response options such as bioenergy and BECCS and some risk sharing instruments, such as crop insurance, trade-off over multiple SDG with potentially significant adverse consequences.

Overall, across both categories of both SDG and NCP, 17 of 40 options deliver co-benefits or no adverse side-effects for the full range of NCP and SDG. This include most agriculture- and soil-based land management options, many ecosystem-based land management options, improved forest management, reduced post-harvest losses, sustainable sourcing, improved energy use in food systems, and livelihood diversification. Only three options (afforestation, bioenergy and BECCS and some types of risk sharing instruments, such as crop insurance) have potentially adverse side-effects for five or more NCP or SDG.

LEGEND:

1 6.4.4 Opportunities for implementation of Integrated Response Options

2 6.4.4.1 Where can the response options be applied?

3 As shown in Section 6.1.3, a large part of the land area is exposed to overlapping land challenges, especially in villages, croplands and rangelands. The deployment of land management responses may vary with local exposure to land challenges. For instance, with croplands exposed to a combination of land degradation, food insecurity and climate change adaptation challenges, maximising the co-benefits of land management responses would require selecting responses having only co-benefits for these 3 overlapping challenges, as well as for climate change mitigation which is a global challenge. Based on these criteria, Figure 6.6 shows the potential deployment area of land management responses across land use types (or anthromes).

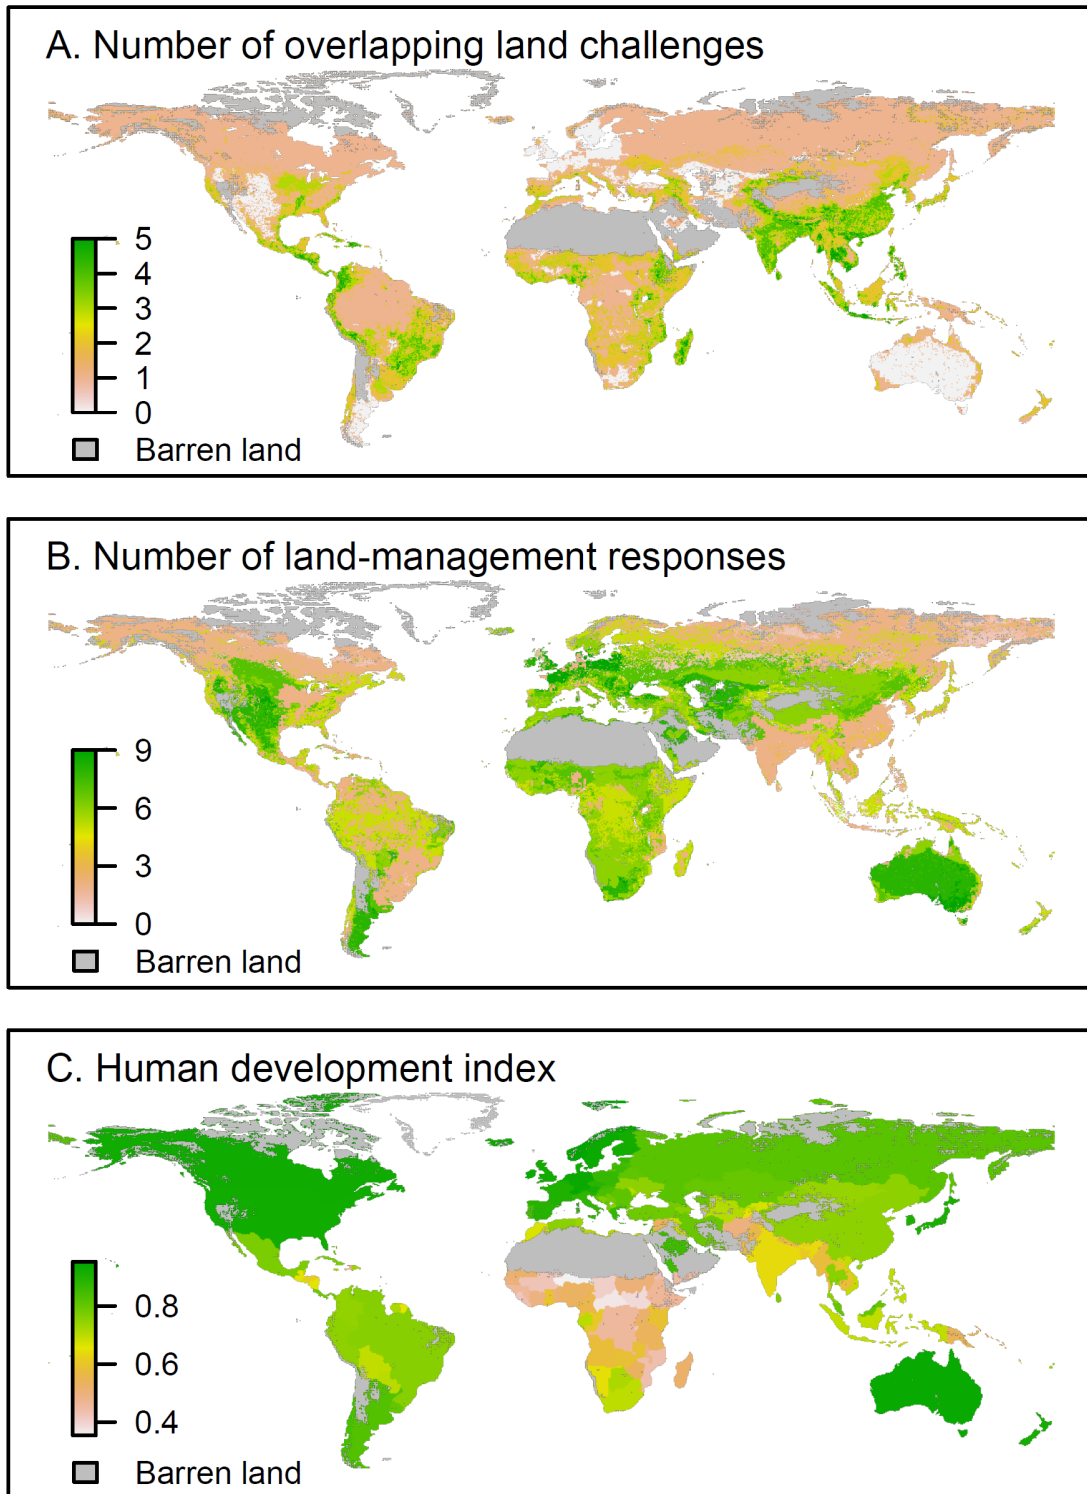

11
12 **Figure 6.6 Potential deployment area of land management responses (see Table 6.1) across land use types (or**
13 **anthromes, see section 6.3), when selecting responses having only co-benefits for local challenges and for**
14 **climate change mitigation and no large adverse side-effect on global food security. See Figure 6.2 for the**
15 **criteria used to map challenges (desertification, land degradation, climate change adaptation, chronic**
16 **undernourishment, biodiversity, groundwater stress and water quality) considered. No response option was**
17 **identified for barren lands.**

18 Land management responses having co-benefits across the range of challenges, including climate change
19 mitigation, could be deployed between one (coastal wetlands, peatlands, forest management and
20 restoration, reforestation) and 5 (increased soil organic carbon) or 6 (fire management) land use types
21 (Figure 6.6). Fire management and increased soil organic carbon have a large potential since they could
22 be deployed with mostly co-benefits and few adverse effects over 76 and 58% of the ice-free land area. In
23 contrast, other responses have a limited area-based potential due to biophysical constraints (e.g., limited
24 extent of organic soils and of coastal wetlands for conservation and restoration responses), or due to the
25 occurrence of adverse effects. Despite strong co-benefits for climate change mitigation, the deployment of
26 bioenergy and BECCS would have co-benefits on only 9% of the ice-free land area (Figure 6.6), given
27 adverse effects of this response option for food security, land degradation, climate change adaptation and
28 desertification (see Tables 6.62-6.69).

1 Without including the global climate change mitigation challenge, there are up to 5 overlapping
2 challenges on lands which are not barren (Fig. 6.7A, calculated from the overlay of individual challenges
3 shown in Fig. 6.2) and up to 9 land management response options having only co-benefits for these
4 challenges and for climate change mitigation (Fig. 6.7B). Across countries, the mean number of land
5 management response options with mostly co-benefits declines ($p < 0.001$, Spearman rank order
6 correlation) with the mean number of land challenges. Hence, the higher the number of land challenges
7 per country, the fewer the land management response options having only co-benefits for the challenges
8 encountered.

9
10 Enabling conditions (see Section 6.1.2.2) for the implementation of land management responses partly
11 depend upon human development (economics, health and education) as estimated by a country scale
12 composite index, the Human Development index (HDI, United Nations Development Program, 2018)
13 (Figure 6.7C). Across countries, HDI is negatively correlated ($p < 0.001$, Spearman rank order correlation)
14 with the mean number of land challenges. Therefore, on a global average, the higher the number of local
15 challenges faced, the fewer the land management responses having only co-benefits and the lower the
16 human development (Figure 6.7) that could favour the implementation of these responses.

17

1
 2 **Figure 6.7 Global distributions of (A) number of overlapping land challenges (desertification, land**
 3 **degradation, climate change adaptation, chronic undernourishment, biodiversity, groundwater stress and**
 4 **water quality, see Fig. 6.2); (B) number of land management responses providing medium to large co-benefits**
 5 **and no adverse side-effects (see Fig. 6.6) across challenges; (C) Human Development Index (HDI) by country.**
 6 **The Human Development Index (United Nations Development Programme, 2018) is a country based**
 7 **composite statistical index measuring average achievement in three basic dimensions of human development**

1 **a long and healthy life (estimated from life expectancy at birth), knowledge (estimated from years of**
 2 **schooling) and a decent standard of living (estimated from gross national income per capita)**

3 **6.4.4.2 Interlinkages and response options in future scenarios**

4 This section assesses more than eighty articles quantifying the effect of various response options in the
 5 future, covering a variety of response options and land-based challenges. These studies cover spatial
 6 scales ranging from global (Popp et al. 2017; Fujimori et al. 2018a) to regional (Calvin et al. 2016a; Frank
 7 et al. 2015) to country-level (Gao and Bryan 2017; Pedercini et al. 2018). This section focuses on models
 8 that can quantify interlinkages between response options, including agricultural economic models, land
 9 system models, and integrated assessment models. The IAM and non-IAM literature, however, is also
 10 categorised separately to elucidate what is and is not included in global mitigation scenarios, like those
 11 included in the SR15. Results from bottom-up studies and models (e.g., Griscom et al. 2017a) are
 12 assessed in Section 6.2-6.3.

13 *Response options in future scenarios:*

14 More than half of the 40 land-based response options discussed in this chapter are represented in global
 15 IAMs models used to develop and analyse future scenarios, either implicitly or explicitly (Table 6.76).
 16 For example, all IAMs include improved cropland management, either explicitly through technologies
 17 that improve N use efficiency (Humpenöder et al. 2018a) or implicitly through marginal abatement cost
 18 curves that link reductions in N₂O emissions from crop production to carbon prices (most other models).

19 However, the literature discussing the effect of these response options on land-based challenges is more
 20 limited (Table 6.76). Fifty-seven studies (forty-three IAM studies) articulate the effect of response options
 21 on mitigation, with most including bioenergy and BECCS or a combination of reduced deforestation,
 22 reforestation, and afforestation. Thirty-seven studies (twenty-one IAM studies) discuss the implications of
 23 response options on food security, usually using food price as a metric. While a small number of non-
 24 IAM studies examine the effects of response options on desertification (three studies) and land
 25 degradation (five studies), no IAM studies were identified. However, some studies quantify these
 26 challenges indirectly using IAMs either via climate outputs from the RCPs (Huang et al. 2016) or by
 27 linking IAMs to other land and ecosystem models (Brink et al. 2018; UNCCD 2017).

28 For many of the scenarios in the literature, land-based response options are included as part of a suite of
 29 mitigation options (Popp et al. 2017; van Vuuren et al. 2015a). As a result, it is difficult to isolate the
 30 effect of an individual option on land-related challenges. A few studies focus on specific response options
 31 (Calvin et al. 2014a; Popp et al. 2014b; Kreidenweis et al. 2016b; Humpenöder et al. 2018a), quantifying
 32 the effect of including an individual option on a variety of sustainability targets.

33
 34 **Table 6.76 Number of IAM and non-IAM Studies Including Specific Response Options (rows) and**
 35 **Quantifying Particular Land Challenges (columns). The third column shows how many IAM models include**
 36 **the individual response option; red indicates all models include the option, orange indicates more than half of**
 37 **all models, yellow indicates less than half, and white indicates no models. The remaining columns show**
 38 **challenges related to climate change (C), mitigation (M), adaptation (A), desertification (D), land degradation**
 39 **(L), food security (F), and biodiversity/ecosystem services/sustainable development (B). The colour indicates**
 40 **the number of total studies, with 0 (white), 1-5 (green), 6-10 (light blue), 11-15 (dark blue), and 16 or more**
 41 **(purple). Additionally, counts of total (left value) and IAM-only (right value) studies are included. Some**
 42 **IAMs include agricultural economic models which can also be run separately; these models are not counted**
 43 **as IAM literature when used on their own. Studies using a combination of IAMs and non-IAMs are included**
 44 **in the total only. A complete list of studies is included in the supplementary material.**

1 ^a Only IAMs that are used in the papers assessed are included in this column.
 2 ^b There are many indicators for land degradation (see Chapter 4). In this table, studies are categorised as quantifying
 3 land degradation if they explicitly discuss land degradation.
 4 ^c Studies are categorised as quantifying food security if they report food prices or the population at risk of hunger.
 5

6 *Interactions and Interlinkages between Response Options:*

7 The effect of response options on desertification, land degradation, food security, biodiversity, and other
 8 sustainable development goals depends strongly on which options are included and the extent to which
 9 they are deployed. For example, sections 2.6, 6.3.6, and the Cross-Chapter Box 7 on Bioenergy note that
 10 bioenergy and BECCS has a large mitigation potential but could potentially have adverse side effects for
 11 land degradation, food security, and other sustainable development goals. Global modelling studies
 12 demonstrate that these effects are dependent on scale. Increased use of bioenergy can result in increased
 13 mitigation (Figure 6.8, Panel A) and reduced climate change, but can also lead to increased energy
 14 cropland expansion (Figure 6.8, Panel B), and increased competition for land resulting in increased food
 15 prices (Figure 6.8, Panel C). However, the exact relationship between bioenergy deployment and each
 16 sustainability target depends a number of other factors, including the feedstock used, the underlying
 17 socioeconomic scenario, assumptions about technology and resource base, the inclusion of other response
 18 options, and the specific model used (Calvin et al. 2014a; Clarke and Jiang 2014b; Popp et al. 2014b,
 19 2017; Kriegler et al. 2014).

20
 21 **Figure 6.8 Correlation between Bioenergy Use and Other Indicators.** Panel A shows global CO₂ sequestration
 22 by BECCS in 2100. Panel B shows global energy cropland area in 2100. Panel C shows agricultural prices in
 23 2100 indexed to 2010. Data are binned based on the amount of bioenergy used globally in 2100. All scenario
 24 data that include both bioenergy consumption and the variable of interest are included in the figure; the
 25 resulting number of scenarios varies per panel with 352 in panel A, 262 in panel B, and 172 in panel C. The

1 **boxes represent the interquartile range (i.e., the middle 50% of all scenarios), the line in the middle of the box**
2 **represents the median, and the whiskers represent the 5 to 95% range of scenarios. Data is from an update of**
3 **the IAMC Scenario Explorer developed for the SR15 (Huppmann et al. 2018; Rogelj et al. 2018b).**

4 The previous sections have examined the effects of individual land-response options on multiple
5 challenges. A number of studies using global modelling and analyses have examined interlinkages and
6 interaction effects among land response options by incrementally adding or isolating the effects of
7 individual options. Most of these studies focus on interactions with bioenergy and BECCS (Table 6.77).
8 Adding response options that require land (e.g., reforestation, afforestation, reduced deforestation,
9 avoided grassland conversion, or biodiversity conservation), results in increased food prices (Calvin et al.
10 2014a; Humpenöder et al. 2014a; Obersteiner et al. 2016a; Reilly et al. 2012a) and potentially increased
11 temperature through biophysical climate effects (Jones et al. 2013). However, this combination can result
12 in reduced water consumption (Hejazi et al. 2014c), reduced cropland expansion (Calvin et al. 2014a;
13 Humpenöder et al. 2018a), increased forest cover (Calvin et al. 2014a; Humpenöder et al. 2018a; Wise et
14 al. 2009a) and reduced biodiversity loss (Pereira et al. 2010), compared to scenarios with bioenergy and
15 BECCS alone. While these options increase total mitigation, they reduce mitigation from bioenergy and
16 BECCS as they compete for the same land (Wu et al. 2019; Baker et al. 2019a; Calvin et al. 2014a;
17 Humpenöder et al. 2014a).

18 The inclusion of land-sparing options (e.g., dietary change, increased food productivity, reduced food
19 waste, management of supply chains) in addition to bioenergy and BECCS results in reduced food prices,
20 reduced agricultural land expansion, reduced deforestation, reduced mitigation costs, reduced water use,
21 and reduced biodiversity loss (Bertram et al. 2018; Wu et al. 2019; Obersteiner et al. 2016a; Stehfest et al.
22 2009; van Vuuren et al. 2018a). These options can increase bioenergy potential, resulting in increased
23 mitigation than from bioenergy and BECCS alone (Wu et al. 2019; Stehfest et al. 2009; Favero and
24 Massetti 2014).

25 Other combinations of land response options create synergies, alleviating land pressures. The inclusion of
26 increased food productivity and dietary change can increase mitigation, reduce cropland use, reduce water
27 consumption, reduce fertiliser application, and reduce biodiversity loss (Springmann et al. 2018c;
28 Obersteiner et al. 2016a). Similarly, improved livestock management combined with increased food
29 productivity can reduce agricultural land expansion (Weindl et al. 2017). Reducing disturbances (e.g., fire
30 management) in combination with afforestation can increase the terrestrial carbon sink, resulting in
31 increased mitigation potential and reduced mitigation cost (Le Page et al. 2013a).

32 Studies including multiple land response options often find that the combined mitigation potential is not
33 equal to the sum of individual mitigation potential as these options often share the same land. For
34 example, including both afforestation and bioenergy and BECCS results in a cumulative reduction in
35 GHG emissions of 1200 GtCO₂ between 2005 and 2100, which is much lower than the sum of the
36 contributions of bioenergy (800 GtCO₂) and afforestation (900 GtCO₂) individually (Humpenöder et al.
37 2014a). More specifically, Baker et al. (2019a) find that woody bioenergy and afforestation are
38 complementary in the near-term, but become substitutes in the long-term, as they begin to compete for the
39 same land. Similarly, the combined effect of increased food productivity, dietary change, and reduced
40 waste on GHG emissions is less than the sum of the individual effects (Springmann et al. 2018c).

1 **Table 6.77 Interlinkages between bioenergy and BECCS and other response options.** Table indicates the
 2 **combined effects of multiple land-response options on climate change (C), mitigation (M), adaptation (A),**
 3 **desertification (D), land degradation (L), food security (F), and biodiversity/ecosystem services/sustainable**
 4 **development (O).** Each cell indicates the implications of adding the option specified in the row in addition to
 5 **bioenergy and BECCS.** Blue colours indicate positive interactions (e.g., including the option in the second
 6 **column increases mitigation, reduces cropland area, or reduces food prices relative to bioenergy and BECCS**
 7 **alone).** Red colours indicate negative interactions; yellow indicates mixed interactions (some positive, some
 8 **negative).** Note that only response option combinations found in the assessed literature are included in the
 9 **interest of space.**

^a Includes changes in biophysical effects on climate (e.g., albedo)

^b Either through reduced emissions, increased mitigation, reduced mitigation cost, or increased bioenergy potential.

For increased mitigation, a positive indicator in this column only indicates that total mitigation increases and not that the total is greater than the sum of the individual options.

^c Uses changes in cropland or forest as an indicator (reduced cropland expansion or reduced deforestation are considered positive)

^d Includes changes in water use or scarcity, fertiliser use, or biodiversity

Land-related response options can also interact with response options in other sectors. For example, limiting deployment of a mitigation response option will either result in increased climate change or additional mitigation in other sectors. A number of studies have examined limiting bioenergy and BECCS. Some such studies show increased emissions (Reilly et al. 2012a). Other studies meet the same climate goal, but reduce emissions elsewhere *via* reduced energy demand (Grubler et al. 2018; van Vuuren et al. 2018a), increased fossil CCS, nuclear energy, energy efficiency and/or renewable energy (van Vuuren et al. 2018a; Rose et al. 2014b; Calvin et al. 2014a; van Vuuren et al. 2017b), dietary change (van Vuuren et al. 2018a), reduced non-CO₂ emissions (van Vuuren et al. 2018a), or lower population (van Vuuren et al. 2018a). The co-benefits and adverse side-effects of non-land mitigation options are discussed in SR15, Chapter 5. Limitations on bioenergy and BECCS can result in increases in the cost of mitigation (Kriegler et al. 2014; Edmonds et al. 2013a). Studies have also examined limiting CDR, including reforestation, afforestation, and bioenergy and BECCS (Kriegler et al. 2018a,b). These studies find that limiting CDR can increase mitigation costs, increase food prices, and even preclude limiting warming to less than 1.5°C above pre-industrial levels (Kriegler et al. 2018a,b; Muratori et al. 2016).

In some cases, the land challenges themselves may interact with land-response options. For example, climate change could affect the production of bioenergy and BECCS. A few studies examine these effects, quantifying differences in bioenergy production (Calvin et al. 2013a; Kyle et al. 2014) or carbon price (Calvin et al. 2013a) as a result of climate change. Kyle et al. (2014) finds increase in bioenergy production due to increases in bioenergy yields, while Calvin et al. (2013a) finds declines in bioenergy production and increases in carbon price due to the negative effects of climate on crop yield.

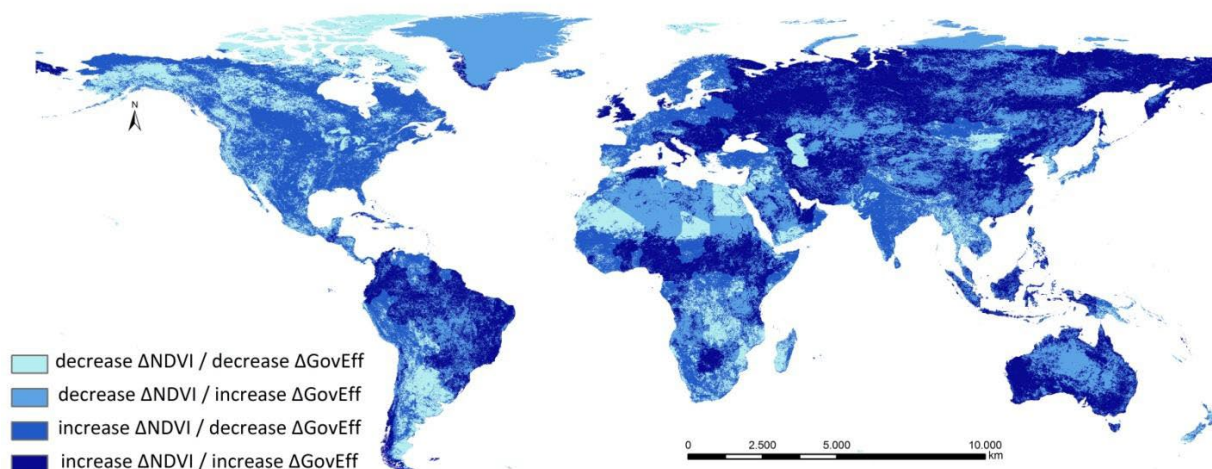

Gaps in the Literature:

Not all of the response options discussed in this chapter are included in the assessed literature, and many response options are excluded from the IAM models. The included options (e.g. bioenergy and BECCS; reforestation) are some of the largest in terms of mitigation potential (see Section 6.3). However, some of the options excluded also have large mitigation potential. For example, biochar, agroforestry, restoration/avoided conversion of coastal wetlands, and restoration/avoided conversion of peatland all have mitigation potential of ~1 GtCO₂ yr⁻¹ (Griscom et al. 2017). Additionally, quantifications of and response options targeting land degradation and desertification are largely excluded from the modelled studies, with a few notable exceptions (Wolff et al. 2018; Gao and Bryan 2017; Brink et al. 2018; UNCCD 2017). Finally, while a large number of papers have examined interactions between bioenergy and BECCS and other response options, the literature examining other combinations of response options is more limited.

6.4.4.3 Resolving challenges in response option implementation

The 40 response options assessed in this chapter face a variety of barriers to implementation that require action across multiple actors to overcome (section 6.4.1). Studies have noted that while adoption of

1 response options by individuals may depend on individual assets and motivation, larger structural and
 2 institutional factors are almost always equally important if not more so (Adimassu et al. 2016; Djenontin
 3 et al. 2018), though harder to capture in research variables (Schwilch et al. 2014). These institutional and
 4 governance factors can create an enabling environment for SLM practices, or challenges to their
 5 adoption (Adimassu et al. 2013). Governance factors include the institutions that manage rules and
 6 policies, the social norms and collective actions of participants (including civil society actors and the
 7 private sector), and the interactions between them (Ostrom 1990; Huntjens et al. 2012; Davies 2016).
 8 Many of Ostrom’s design principles for successful governance can be applied to response options for
 9 SLM; these principles are: (1) clearly defined boundaries; (2) understanding of both benefits and costs;
 10 (3) collective choice arrangements; (4) monitoring; (5) graduated sanctions; (6) conflict-resolution
 11 mechanisms; (7) recognition of rights; and (8) nested (multi-scale) approaches. Unfortunately, studies of
 12 many natural resources and land management policy systems in developing countries in particular often
 13 show the opposite: a lack of flexibility, strong hierarchical tendencies, and a lack of local participation in
 14 institutional frameworks (Ampaire et al. 2017). Analysis of government effectiveness (GE)– defined as
 15 quality of public services, policy formulation and implementation, civil service and the degree of its
 16 independence from political pressures as well as credibility of the government’s commitment to its
 17 policies (Kaufman et al. 2010) – has been shown to play a key role in land management. GE mediates
 18 land user actions on land management and investment, and government policies and laws can help land
 19 users adopt sustainable land management practices (Nkonya et al. 2016) (Figure 6.9).

20
 21 **Figure 6.9 Relationship between changes in government effectiveness and changes in land management**

 23 Source of NDVI data: MODIS Δ GovEff = Change in Government effectiveness (baseline year 2001, Endline year
 24 2010). Source of Government effectiveness: World Bank. Source: Nkonya et al 2016.

25 It is simply not a matter of putting the ‘right’ institutions or policies in place, however, as governance can
 26 be undermined by inattention to power dynamics (Fabinyi et al. 2014). Power shapes how actors gain
 27 access and control over resources, and negotiate, transform and adopt certain response options or not.
 28 These variable dynamics of power between different levels and stakeholders have an impact on the ability
 29 to implement different response options. The inability of many national governments to address social
 30 exclusion in general will have an effect on the implementation of many response options. Further,
 31 response options themselves can become avenues for actors to exert power claims over others

1 (Nightingale 2017). For example, there have been many concerns that reduced deforestation and
2 degradation projects run the risk of reversing trends towards decentralisation in forest management and
3 create new power disparities between the state and local actors (Phelps et al. 2010). Below we assess how
4 two important factors, the involvement of stakeholders and the coordination of action across scales, will
5 help in moving from response options to policy implementation, a theme chapter 7 takes up in further
6 detail.

7 *Involvement of stakeholders*

8 There are a wide range of stakeholders that are necessary for successful land, agricultural and
9 environmental policy, and implementing response options requires that a range of actors, including
10 businesses, consumers, land managers, indigenous and local communities, scientists, and policymakers
11 work together for success. Diverse stakeholders have a particularly important role to play in defining
12 problems, assessing knowledge and proposing solutions (Phillipson et al. 2012; Stokes et al. 2006). Lack
13 of connection between science knowledge and on-the-ground practice has hampered adoption of many
14 response options in the past; simply presenting ‘scientifically’ derived response options is not enough
15 (Marques et al. 2016). For example, the importance of recognising and incorporating local knowledge
16 (LK) and indigenous knowledge (IK) is increasingly emphasised in successful policy implementation (see
17 Cross-Chapter Box 13 on Indigenous Knowledge, Chapter 7), as local practices of water management,
18 soil fertility management, improved grazing, restoration and sustainable management of forests are often
19 well-aligned with response options assessed by scientists (Marques et al. 2016).

20 Stakeholder engagement is an important approach for successful environmental and climate policy and
21 planning. Tools such as stakeholder mapping, in which affected and interested parties are identified and
22 described in terms of their interrelationships and current or future objectives and aspirations, and
23 scenario-based stakeholder engagement, which combines stakeholder analysis with climate scenarios, are
24 increasingly being applied to facilitate better planning outcomes (Tompkins et al. 2008; Pomeroy &
25 Douvere 2008; Star et al. 2016). Facilitated dialogues early in design processes have shown good success
26 in bringing multiple and sometimes conflicting stakeholders to the table to discuss synergies and trade-
27 offs around policy implementation (Gopnik et al 2012). Knowledge exchange, social learning, and other
28 concepts are also increasingly being incorporated into understandings of how to facilitate sustainable land
29 management (Djenontin et al. 2018), as evidence suggests that negotiating the complexity of SESs
30 requires flexible learning arrangements in particular for multiple stakeholders (Gerlak and Heikkila 2011;
31 Armitage et al. 2018; Heikkila and Gerlak 2018). Social learning has been defined as “a change in
32 understanding and skills that becomes situated in groups of actors/communities of practice through social
33 interactions,” (Albert et al. 2012), and social learning is often linked with attempts to increase levels of
34 participation in decision making, from consultation to more serious community control (Collins and Ison
35 2009; McCrum et al. 2009). Learning also facilitates responses to emerging problems and helps actors in
36 SESs grapple with complexity. One outcome of learning can be adaptive risk management (ARM), in
37 which “one takes action based on available information, monitors what happens, learns from the
38 experience and adjusts future actions based on what has been learnt” (Bidwell et al. 2013). Suggestions to
39 facilitate social learning, ARM, and decision-making include extending science-policy networks and
40 using local bridging organisations, such as extension services, for knowledge co-production (Bidwell et
41 al. 2013; Böcher and Krott 2014; Howarth and Monasterolo 2017) see further discussion in Chapter 7,
42 section 7.5 on Decision-making for Climate and Land).

43

1 Insuring that women are included as key stakeholders in response option implementation is also
2 important, as gender norms and roles affect vulnerability and access to resources, and gender inequality
3 limits the possible range of responses for adoption by women (Lambrou and Piana 2006). For example,
4 environmental change may increase women’s workload as their access to natural resources may decline,
5 or they may have to take up low-wage labour if agriculture becomes unsuitable in their local areas under
6 climate change (Nelson et al. 2002). Every response option considered in this chapter potentially has a
7 gender dimension to it that needs to be taken into consideration (Tables 6.73–6.75 note how response
8 options intersect with SDG 5 Gender Equity); for example, to address food security through sustainable
9 intensification will clearly have to address women farmers in Africa (Kondylis et al. 2016; Garcia and
10 Wanner 2017) (For further information, see Cross-Chapter Box 11: Gender, in Chapter 7).

11 *Challenges of coordination*

12 Coordinated action to implement the response options will be required across a range of actors, including
13 business, consumers, land managers, indigenous and local communities and policymakers to create
14 enabling conditions. Conjoining response options to maximise social, climatic and environmental
15 benefits will require framings of such actions as strong pathways to sustainable development (Ayers and
16 Dodman 2010). As the chapter has pointed out, there are many potentials for synergies, especially among
17 several response options that might be applied together and in coordination with one another (such as
18 dietary change and improved land management measures). This coordination will help ensure that
19 synergies are met and trade-offs minimised, but this will require deliberate coordination across multiple
20 scales, actors and sectors. For example, there are a variety of response options available at different
21 scales that could form portfolios of measures applied by different stakeholders from farm to international
22 scales. Agricultural diversification and use of local seeds by smallholders can be particularly useful
23 poverty reduction and biodiversity conservation measures, but are only successful when higher scales,
24 such as national and international markets and supply-chains, also value these goods in trade regimes,
25 and consumers see the benefits of purchasing these goods. However, the land and food sectors face
26 particular challenges of institutional fragmentation, and often suffer from a lack of engagement between
27 stakeholders at different scales (Biermann et al. 2009; Deininger et al 2014) (see section 7.6.2, Chapter
28 7).

29 Many of the response options listed in this chapter could be potentially implemented as ‘community-
30 based’ actions, including community-based reforestation, community-based insurance, or community-
31 based disaster risk management. Grounding response options in community approaches aims to identify,
32 assist and implement activities “that strengthen the capacity of local people to adapt to living in a riskier
33 and less predictable climate” (Ayers and Forsyth 2009). Research that shows that people willingly come
34 together to provide mutual aid and protection against risk, to manage natural resources, and to work
35 cooperatively to find solutions to environmental provisioning problems. Some activities that fall under
36 this type of collective action can include the creation of institutions or rules; working cooperatively to
37 manage a resource by restricting some activities and encouraging others; sharing information to improve
38 public goods; or mobilising resources, such as capital, to fix a collective problem (Ostrom 2000; Poteete
39 and Ostrom 2004); or engagement in participatory land use planning (Bourgoin 2012; Evers and
40 Hofmeister 2011). These participatory processes “are likely to lead to more beneficial environmental
41 outcomes through better informed, sustainable decisions, and win-win solutions regarding economic and
42 conservation objectives” (Vente et al. 2016), and evaluations of community-based response options have
43 been generally positive (Karim and Thiel 2017a; Tompkins & Adger 2004).

1 Agrawal (2001) has identified more than 30 different indicators that have been important in understanding
2 who undertakes collective action for the environment, including the size of the group undertaking action;
3 the type and distribution of the benefits from the action; the heterogeneity of the group; the dependence of
4 the group on these benefits; the presence of leadership; presence of social capital and trust; and autonomy
5 and independence to make and enforce rules. Alternatively, when households expect the government to
6 undertake response actions, they have less incentive to join in collective action, as the state role has
7 ‘crowded out’ local cooperation (Adger 2009). High levels of social trust and capital can increase
8 willingness of farmers to engage in response options, such as improved soil management or carbon
9 forestry (Stringer et al. 2012; Lee 2017), and social capital helps with connectivity across levels of SESs
10 (Brondizio et al. 2009). (Dietz et al. 2013) lay out important policy directions for more successful
11 facilitation of collective action across scales and stakeholders. These include: providing information;
12 dealing with conflict; inducing rule compliance; providing physical, technical or institutional
13 infrastructure; and being prepared for change. The adoption of participatory protocols and structured
14 processes to select response options together with stakeholders will likely lead to greater success in
15 coordination and participation (Bautista et al. 2017; Franks 2010; Schwilch et al. 2012a).

16 However, wider adoption of community-based approaches is potentially hampered by several factors: the
17 fact that most are small scale (Forsyth 2013; Ensor et al. 2014) and it is often unclear how to assess
18 criteria of success (Forsyth 2013). Others also caution that community-based approaches often are not
19 able to adequately address the key drivers of vulnerability such as inequality and uneven power relations
20 (Nagoda and Nightingale 2017).

21 *Moving from response options to policies*

22 Chapter 7 discusses in further depth the risks and challenges involved in formulating policy responses that
23 meet the demands for sustainable land management and development outcomes, such as food security,
24 community adaptation and poverty alleviation. Chapter 7 in Table 7.1 maps how specific response options
25 might be turned into policies; for example, to implement a response option aimed at agricultural
26 diversification, a range of policies from elimination of agricultural subsidies (which might favour single
27 crops) to environmental farm programs and agro-environmental payments (to encourage alternative
28 crops). Oftentimes, any particular response option might have a variety of potential policy pathways that
29 might address different scales or stakeholders or take on different aspects of coordination and integration
30 (section 7.6.1). Given the unique challenges of decision-making under uncertainty in future climate
31 scenarios, Chapter 7 particularly discusses the need for flexible, iterative, and adaptive processes to turn
32 response options into policy frameworks.

33

34 **Cross-Chapter Box 9: Illustrative Climate and Land Pathways**

Katherine Calvin (The United States of America), Edouard Davin (France/Switzerland), Margot Hurlbert (Canada), Jagdish Krishnaswamy (India), Alexander Popp (Germany), Prajal Pradhan (Nepal/Germany)

Future development of socioeconomic factors and policies influence the evolution of the land-climate system, among others in terms of the land used for agriculture and forestry. Climate mitigation policies can also have a major impact on land use, especially in scenarios consistent with the climate targets of the

Paris Agreement. This includes the use of bio-energy or Carbon Dioxide Removal (CDR), such as bioenergy with carbon dioxide capture and storage (BECCS) and afforestation. Land-based mitigation options have implications for GHG fluxes, desertification, land degradation, food insecurity, ecosystem services and other aspects of sustainable development.

Illustrative Futures

The three illustrative futures are based on the Shared Socioeconomic Pathways (SSPs; (O'Neill et al. 2014c; Riahi et al. 2017b; Popp et al. 2017; Rogelj et al. 2018b); Cross-Chapter Box 1 in Chapter 1). SSP1 is a scenario with a broad focus on sustainability including a focus on human development, technological development, nature conservation, globalised economy, economic convergence and early international cooperation including moderate levels of trade. The scenario assumes a low population growth, relatively high agricultural yields and a move towards less-meat intensive diets (van Vuuren et al. 2017b). Dietary change and reductions in food waste reduce agricultural demands and well-managed land systems enable reforestation and/or afforestation. SSP2 is a scenario in which societal as well as technological development follows historical patterns (Fricko et al. 2017). Land-based CDR is achieved through bioenergy and BECCS, and to a lesser degree by afforestation and reforestation. SSP3 is a scenario with limited technological progress and land-use regulation. Agricultural demands are high due to resource-intensive consumption and a regionalised world leads to reduced flows for agricultural goods. In SSP3, forest mitigation activities and abatement of agricultural GHG emissions are limited due to major implementation barriers such as low institutional capacities in developing countries and delayed as a consequence of low international cooperation (Fujimori et al. 2017a). Emissions reductions are achieved primarily through the energy sector, including the use of bioenergy and BECCS.

Policies in the Illustrative Futures

SSPs are complemented by a set of shared policy assumptions (Kriegler et al. 2014), indicating the types of policies that may be implemented in each future world. IAMs represent the effect of these policies on the economy, energy system, land use and climate with the caveat that they are assumed to be effective or in some cases the policy goals (e.g., dietary change) are imposed rather than explicitly modelled. In the real world, there are various barriers that can make policy implementation more difficult (see 7.4.9). These barriers will be generally higher in SSP3 than SSP1.

SSP1: A number of policies could support this SSP1 future including: effective carbon pricing, emission trading schemes (including net CO₂ emissions from agriculture), carbon taxes, regulations limiting GHG emissions and air pollution, forest conservation (mix of land-sharing and land sparing) through participation, incentives for ecosystem services and secure tenure, and protecting the environment, microfinance, crop and livelihood insurance, agriculture extension services, agricultural production subsidies, low export tax and import tariff rates on agricultural goods, dietary awareness campaigns, regulations to reduce and taxes on food waste, improved shelf life, sugar/fat taxes, and instruments supporting sustainable land management including payment for ecosystem services, land use zoning, REDD+, standards and certification for sustainable biomass production practices, legal reforms on land ownership and access, legal aid, legal education, including reframing these policies as entitlements for women and small agricultural producers (rather than sustainability) (O'Neill et al. 2017; van Vuuren et al. 2017b) (see 7.4).

SSP2: The same policies that support the SSP1 could support the SSP2 but may be less effective and only moderately successful. Policies may be challenged by adaptation limits (7.4.9), inconsistency in formal and informal institutions in decision making (7.5.1) or result in maladaptation (7.4.7). Moderately successful sustainable land management policies result in some land competition. Land degradation

neutrality is moderately successful. Successful policies include those supporting bioenergy and BECCS (Rao et al. 2017; Riahi et al. 2017b; Fricko et al. 2017) (see 7.4.6).

SSP3: Policies that exist in SSP1 may or may not exist in SSP3, and are ineffective (O'Neill et al. 2014c). There are challenges to implementing these policies, as in SSP2. In addition, ineffective sustainable land management policies result in competition for land between agriculture and mitigation. Land degradation neutrality is not achieved (Riahi et al. 2017b). Successful policies include those supporting bioenergy and BECCS (see 7.4.6) (Kriegler et al. 2017; Fujimori et al. 2017a; Rao et al. 2017). Demand side food policies are absent and supply side policies predominate. There is no success in advancing land ownership and access policies for agricultural producer livelihood (7.6.5).

Land use and land cover change

Agricultural area in SSP1 declines as a result of the low population growth, agricultural intensification, low meat consumption, and low food waste. In contrast, SSP3 has high population and strongly declining rates of crop yield growth over time, resulting in increased agricultural land area. The SSP2 falls somewhere in between, with its modest growth in all factors. In the climate policy scenarios consistent with the Paris Agreement, bioenergy/BECCS and reforestation/afforestation play an important role in SSP1 and SSP2. The use of these options, and the impact on land, is larger in scenarios that limit radiative forcing in 2100 to 1.9 Wm^{-2} than in the 4.5 Wm^{-2} scenarios. In SSP3, the expansion of land for agricultural production implies that the use of land-related mitigation options is very limited, and the scenario is characterised by continued deforestation.

Cross-Chapter Box 9 Figure 1: Changes in agricultural land (left), energy cropland (middle) and forest cover (right) under three different SSPs (colours) and two different warming levels (rows). Agricultural land includes both pasture and non-energy cropland. Colours indicate SSPs, with SSP1 shown in green, SSP2 in blue, and SSP3 in red. Shaded area show the range across all IAMs; lines show the median across all models. Models are only included in a figure if they provided results for all SSPs in that panel. There is no SSP3 in the

top row, as 1.9 Wm⁻² is infeasible in this world. Data is from an update of the IAMC Scenario Explorer developed for the SR15 (Huppmann et al. 2018; Rogelj et al. 2018a).

Implications for mitigation and other land challenges

The combination of baseline emissions development, technology options, and policy support makes it much easier to reach the climate targets in the SSP1 scenario than in the SSP3 scenario. As a result, carbon prices are much higher in SSP3 than in SSP1. In fact, the 1.9 Wm⁻² target was found to be infeasible in the SSP3 world (Cross-Chapter Box 9 Table 1). Energy system CO₂ emissions reductions are greater in the SSP3 than in the SSP1 to compensate for the higher land-based CO₂ emissions.

Accounting for mitigation and socioeconomics alone, food prices (an indicator of food insecurity) are higher in SSP3 than in the SSP1 and higher in the 1.9 Wm⁻² than in the 4.5 Wm⁻² (Cross-Chapter Box 9 Table 1). Forest cover is higher in the SSP1 than the SSP3 and higher in the 1.9 Wm⁻² than in the 4.5 Wm⁻². Water withdrawals and water scarcity are in general higher in the SSP3 than the SSP1 (Hanasaki et al. 2013a; Graham et al. 2018b) and higher in scenarios with more bioenergy (Hejazi et al. 2014c); however, these indicators have not been quantified for the specific SSP-RCP combinations discussed here.

Climate change, results in higher impacts and risks in the 4.5 Wm⁻² world than in the 1.9 Wm⁻² world for a given SSP and these risks are exacerbated in SSP3 compared to SSP1 and SSP2 due to population's higher exposure and vulnerability. For example, the risk of fire is higher in warmer worlds; in the 4.5 Wm⁻² world, the population living in fire prone regions is higher in the SSP3 (646 million) than in the SSP2 (560 million) (Knorr et al. 2016). Global exposure to multi-sector risk quadruples between the 1.5°C¹⁰ and 3°C and is a factor of six higher in the SSP3-3°C than in the SSP1-1.5°C (Byers et al. 2018). Future risks resulting from desertification, land degradation and food insecurity are lower in the SSP1 compared to SSP3 at the same level of warming. For example, the transition moderate to high risk of food insecurity occurs between 1.3 and 1.7°C for the SSP3, but not until 2.5 to 3.5°C in the SSP1 (Section 7.2).

Table 1: Quantitative indicators for the illustrative pathways. Each cell shows the mean, minimum, and maximum value across IAM models for each indicator and each pathway in 2050 and 2100. All IAMs that provided results for a particular pathway are included here. Note that these indicators exclude the implications of climate change. Data is from an update of the IAMC Scenario Explorer developed for the SR15 (Huppmann et al. 2018; Rogelj et al. 2018b).

^a The SSP2-19 is infeasible in two models. One of these models sets the maximum carbon price in the SSP1-19; the carbon price range is smaller for the SSP2-19 as this model is excluded there. Carbon prices are higher in the SSP2-19 than the SSP1-19 for every model that provided both simulations.

^a Food demand estimates include waste.

^b Animal product demand includes meat and dairy.

Summary

Future pathways for climate and land use include portfolios of response and policy options. Depending on the response options included, policy portfolios implemented, and other underlying socioeconomic drivers, these pathways result in different land-use consequences and their contribution to climate change mitigation. Agricultural area declines by more than 5 Mkm² in one SSP but increases by as much as 5 Mkm² in another. The amount of energy cropland ranges from nearly zero to 11 Mkm², depending on the SSP and the warming target. Forest area declines in the SSP3 but increases substantially in the SSP1. Subsequently, these pathways have different implications for risks related to desertification, land degradation, food insecurity, and terrestrial greenhouse gas fluxes, as well as ecosystem services, biodiversity, and other aspects of sustainable development.

- 1
- 2 **6.4.5 Potential Consequences of Delayed Action**
- 3 Delayed action, both in terms of overall GHG mitigation across both land and energy sectors, as well as
- 4 delayed action in implementing the specific response options outlined in this chapter, will exacerbate the
- 5 existing land challenges due to the continued impacts of climate change and socioeconomic and other
- 6 pressures; can decrease the potential of response options and increase the costs of deployment; and will
- 7 deprive communities of immediate co-benefits, among other pressures. The major consequences of
- 8 delayed action are outlined below:
- 9 *Delayed action exposes vulnerable people to continued and increasing climate impacts:* Slower or
- 10 delayed action in implementing response options exacerbates existing inequalities and impacts and will
- 11 increase the number of people vulnerable to climate change, due to population increases and increasing
- 12 climate impacts (SR15; AR 5). Future climate change will lead to exacerbation of the existing land

1 challenges, increased pressure on agricultural livelihoods, potential for rapid land degradation, and
2 millions more people exposed to food insecurity (Chapters 3, 4, 5; Schmidhuber & Tubiello 2007). Delay
3 can also bring political risks and significant social impacts, including risks to human settlements
4 (particularly in coastal areas), large-scale migration, and conflict (Barnett & Adger 2007; Hsaing et al.
5 2013). Early action reducing vulnerability and exposure can create an opportunity for a virtual circle of
6 benefits: increased resilient livelihoods, reduced degradation of land, and improved food security (Bohle
7 et al 1994).

8 *Delayed action increases requirements for adaptation:* Failure to mitigate climate change will increase
9 requirements for adaptation. For example, it is likely that by 2100 with no mitigation or adaptation, 31–69
10 million people world-wide could be exposed to flooding (Rasmussen et al., 2018; SR15; Chapter 3); such
11 outcomes could be prevented with investments in both mitigation and adaptation now. Some specific
12 response options (e.g., reduced deforestation and degradation, reduced peatland and wetland conversion)
13 prevent further detrimental effects to the land surface; delaying these options could lead to increased
14 deforestation, conversion, or degradation, serving as increased sources of GHGs and having concomitant
15 negative impacts on biodiversity and ecosystem services (section 6.2). Response options that aim at land
16 restoration and rehabilitation can serve as adaptation mechanisms for communities facing climatic
17 stresses like precipitation variability and changes in land quality, as well as providing benefits in terms of
18 mitigation.

19 *Delayed action increases response costs and reduces economic growth:* Early action on reducing
20 emissions through mitigation is estimated to result in both smaller temperature increases as well as lower
21 mitigation costs than delayed action (Sanderson et al. 2016; Luderer et al. 2013; Fujimori et al., 2016;
22 Rose et al., 2017; van Soest et al., 2017; Luderer et al., 2018). The cost of inaction to address mitigation,
23 adaptation, and sustainable land use exceeds the cost of immediate action in most countries, depending on
24 how damage functions and social cost of carbon are calculated (Dell et al. 2023; Moore & Diaz
25 2015). Costs of acting now would be one to two orders of magnitude lower than economic damages from
26 delayed action, including both damage to assets from climate impacts, as well as potentially reduced
27 economic growth, particularly in developing countries (Moore and Diaz 2015; Luderer et al. 2013; 2016).
28 Increased health costs and costs of energy (e.g. to run air-conditioners to combat increased heat waves) in
29 the US by the end of the century alone are estimated to range from 10-58% of US GDP in 2100
30 (Deschênes and Greenstone 2011).

31 Delay also increases the costs of both mitigation and adaptation actions at later dates. In models of
32 climate-economic interactions, deferral of emissions reductions now requires trade-offs leading to higher
33 costs of several orders of magnitude and risks of higher temperatures in the longer term (Luderer et al
34 2013). Further, costs of action are likely to increase over time due to the increased severity of challenges
35 in future scenarios.

36 Conversely, timely responses in implementing response options brings economic benefits. Carbon pricing
37 is one component of economic responses to encourage adoption of response options (Jakob et al. 2016),
38 but carbon pricing alone can induce higher risk in comparison to other scenarios and pathways that
39 include additional targeted sustainability measures, such as promotion of less material- and energy-
40 intensive lifestyles and healthier diets as noted in our response options (Bertram et al. 2018). While short
41 term costs of deployment of actions may increase, better attainment of a broad set of sustainability targets
42 can be achieved through these combined measures (Bertram et al. 2018).

43 There are also investments now that can lead to immediate savings in terms of avoided damages; for
44 example, for each dollar spent on DMR, countries accrue avoided disaster-related economic losses of

1 USD4 or more (Mechler 2016). While they can require upfront investment, the economic benefits of
2 actions to ensure sustainable land management, such as increased soil organic carbon, can more than
3 double the economic value of rangelands and improve crop yields (Chapter 4; section 6.2).

4 *Delayed action reduces future policy space and decreases efficacy of some response options:* The
5 potential for some response options decreases as climate change increases; for example, climate alters the
6 sink capacity for soil and vegetation carbon sequestration, reducing the potential for increased soil
7 organic carbon, afforestation, and reforestation (6.4.2). Additionally, climate change affects the
8 productivity of bioenergy crops, influencing the potential mitigation of bioenergy and BECCS (Section
9 6.4.4).

10 For response options in the supply chain, demand side management, and risk management, while the
11 consequences of delayed action are apparent in terms of continued GHG emissions from drivers, the tools
12 for response options are not made more difficult by delay and could be deployed at any time.
13 Additionally, given increasing pressures on land as a consequence of delay, some policy response options
14 may become more cost effective while others become costlier. For example, over time, land-based
15 mitigation measures like forest and ecosystem protection are likely to increase land scarcity leading to
16 higher food prices, while demand side measures, like reduced impact diets and reducing waste, are less
17 likely to raise food prices in economic models (Stevanović et al. 2017).

18 For risk management, some response options provide timely and rapidly-deployable solutions for
19 preventing further problems, such as disaster risk management and risk sharing instruments. For example,
20 early warning systems serve multiple roles in protecting lives and property and helping people adapt to
21 longer-term climate changes and can be used immediately.

22 *Delaying action can also result in problems of irreversibility of biophysical impacts and tipping points:*
23 Early action provides a potential way to avoid irreversibility - such as degradation of ecosystems that
24 cannot be restored to their original baseline - and tipping points, whereby ecological or climate systems
25 abruptly shift to a new state. Ecosystems, such as peatlands, are particularly vulnerable to irreversibility
26 because of the difficulties of rewetting to original states (Section 6.2), and dryland grazing systems are
27 vulnerable to tipping points when ground cover falls below 50%, after which productivity falls,
28 infiltration declines, and erosion increases (Chapters 3 and 4). Further, tipping points can be especially
29 challenging for human populations to adapt to, given lack of prior experience with such system shifts
30 (Kates et al. 2012; Nuttall 2012).

31 *Policy responses require lead time for implementation; delay makes this worse:* For all the response
32 options, particularly those that need to be deployed through policy implementation, there are unavoidable
33 lags in this cycle. ‘Policy lags’, by which implementation is delayed by the slowness of the policy
34 implementation cycle, are significant across many land-based, response options (Brown et al. 2019).
35 Further, the behavioural change necessary to achieve some demand-side and risk management response
36 options often takes a long time and delay only lengthens this process (Stern 1992; Steg & Vlek 2009). For
37 example, actively promoting the need for healthier and more sustainable diets through individual dietary
38 decisions is an important underpinning and enabling step for future changes, but is likely to be a slow-
39 moving process, and delay in beginning will only exacerbate this.

40 *Delay can lead to lock-in:* Delay in implementation can cause ‘lock-in’ as decisions made today can
41 constrain future development and pathways. For example, decisions made now on where to build
42 infrastructure, make investments and deploy technologies, will have longer-term (decades-long)
43 ramifications due to inertia of capital stocks (van Soest et al. 2017). In tandem, the vulnerability of the
44 poor is likely to be exacerbated by climate change creating a vicious circle of “lock in” whereby an

1 increasing share of the dwindling carbon budget may be needed to assist with improved energy use for the
2 poorest (Lamb and Rao 2015).

3 *Delay can increase the need for widespread deployment of land-based mitigation* (afforestation, BECCS)
4 (IPCC 2018; Streffler et al. 2018): Further delays in mitigation could result in an increased need for CDR
5 options later; for example, delayed mitigation requires a 10% increase in cumulative CDR over the
6 century (IPCC 2018). Similarly, strengthening near-term mitigation effort can reduce the CDR
7 requirements in 2100 by a factor of 2-8 (Streffler et al., 2018). Conversely, scenarios with limited CDR
8 require earlier emissions reductions (van Vuuren et al. 2017b) and may make more stringent mitigation
9 scenarios, like the 1.5C, infeasible (Kriegler et al. 2018a,b).

10

11 **Frequently Asked Questions**

12

13 **FAQ 6.1: What types of land-based options can help mitigate and adapt to climate change?**

14 Land-based options that help mitigate climate change are various and differ greatly in their mitigation
15 potential. The options with the moderate to large mitigation potential, and no adverse side-effects,
16 include options that decrease pressure on land (e.g. by reducing the land needed for food production) and
17 those that help to maintain or increase carbon stores both aboveground (e.g. forest measures,
18 agroforestry, fire management) and belowground (e.g. increased soil organic matter or reduced losses,
19 cropland and grazing land management, urban land management, reduced deforestation and forest
20 degradation). These options also have co-benefits for adaptation by improving health, increasing yields,
21 flood attenuation and reducing urban heat island effects. Another group of practices aim at reducing
22 greenhouse emission sources, such as livestock management or nitrogen fertilisation management. Land-
23 based options delivering climate change adaptation may be structural (e.g. irrigation and drainage
24 systems, flood and landslide control), technological (e.g. new adapted crop varieties, changing planting
25 zones and dates, using climate forecasts), or socio-economic and institutional (e.g. regulation of land use,
26 associativity between farmers). Some adaptation options (e.g. new planting zones, irrigation) may have
27 adverse-side effects for biodiversity and water. Adaptation options may be planned, such as those
28 implemented at regional, national or municipal level (top-down approaches), or autonomous, such as
29 many technological decisions taken by farmers and local inhabitants. In any case, their effectiveness
30 depends greatly on the achievement of resilience against extreme events (e.g. floods, droughts, heat
31 waves, etc.).

32 **FAQ 6.2: Which land-based mitigation measures could affect desertification, land degradation or** 33 **food security?**

34 Some options for mitigating climate change are based on increasing carbon stores both above and below
35 ground, so mitigation is usually related to increases in soil organic matter content and increased land
36 cover by perennial vegetation. There is a direct relationship, with very few or no adverse side-effects for
37 prevention or reversal of desertification and land degradation and the achievement of food security. This
38 is so because both desertification and land degradation are closely associated with soil organic matter
39 losses and the presence of bare ground surfaces. Food security depends on the achievement of healthy
40 crops and high and stable yields over time, which is difficult to achieve in poor soils that are low in
41 organic matter.

42 **FAQ 6.3: What is the role of bioenergy in climate change mitigation and what are its challenges?**

1 Plants absorb carbon as they grow. If plant-based material (biomass) is used for energy, the carbon it
2 absorbed from the atmosphere is released back. Traditional use of bioenergy for cooking and heating is
3 still widespread throughout the world. Modern conversion to electricity, heat, gas and liquid fuels can
4 reduce the need to burn fossil fuels and this can reduce greenhouse gas emissions, helping to mitigate
5 climate change. However, the total amount of emissions avoided depends on the type of biomass, where
6 it is grown, how it is converted to energy, and what type of energy source it displaces. Some types of
7 bioenergy require dedicated land (e.g., canola for biodiesel, perennial grasses, short rotation woody
8 crops), while others can be co-produced or use agricultural or industrial residues (e.g., residues from
9 sugar and starch crops for ethanol, manure for biogas). Depending on where, how, and the amount of
10 bioenergy crops that are grown, the use of dedicated land for bioenergy could compete with food crops
11 or other mitigation options. It could also result in land degradation, deforestation or biodiversity loss. In
12 some circumstances, however, bioenergy can be beneficial for land, for example by increasing soil
13 organic carbon. The use of co-products and residues for bioenergy limits the competition for land with
14 food but could result in land degradation if carbon and nutrient-rich material is removed that would
15 otherwise be left on the land. On the other hand, the by-products of some bioenergy conversion
16 processes can be returned to the land as a fertiliser and may have other co-benefits (e.g. reducing
17 pollution associated with manure slurry).

 4 **Supplementary Information for Section 6.4.1**

5 Section 6.4.1 includes tables of feasibility dimensions for each of the 40 response options. This section includes the supporting material for those
 6 classifications.

7 **Table SM6.1 Feasibility of land management response options in agriculture, considering cost, technological, institutional, socio-cultural and environmental and**
 8 **geophysical barriers and saturation and reversibility**

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical
Increased food productivity				Limited ability to define and measure indicators of sustainable intensification (Barnes and Thomson 2014b)	better access to credit, services, inputs and markets (Schut et al. 2016)	educational (e.g., educational needs of women; Pretty and Bharucha 2014, and cultural / behavioural (Martin et al. 2015)	since increasing food productivity can be limited by climatic and environmental factors (Olesen et al. 2002)
Improved cropland management			USD74 to USD226 ha ⁻¹	e.g., need for further development of nitrification inhibitors (Singh and Verma 2007b)	can be institutional in some regions (e.g., poor sustainability frameworks, Madlener et al. 2006)	educational (e.g., lack of knowledge; Reichardt et al. 2009b) and cultural / behavioural (e.g., promotion of cover crops needs to account for farmers' needs; Roesch-McNally et al. 2017)	e.g., land access (Bryan et al. 2009b; Bustamante et al. 2014c)

Improved grazing land management			< USD1 kg of meat ⁻¹ (Rolfe et al., 2010)	e.g., need for further development of nitrification inhibitors (Singh and Verma 2007b)	can be institutional in some regions (e.g., need for extension services; Ndoro et al., 2014)	educational (e.g., poor knowledge of best animal husbandry practices among farmers; Ndoro et al., 2014), and cultural / behavioural (e.g. strong cultural importance of livestock and traditional practices in some communities (Herrero et al. 2016)	e.g., unless degraded, grazing lands are already closer to saturation than croplands; Smith et al. 2015
Improved livestock management			USD120 to USD621 ha ⁻¹ (Barnhart et al., 2000)	e.g., many dietary additives are still at low technology readiness level; Beauchemin et al., 2008	can be institutional in some regions (e.g., need for extension services; Ndoro et al., 2014),	educational (e.g., poor knowledge of best animal husbandry practices among farmers; Ndoro et al., 2014), and cultural / behavioural (e.g., strong cultural importance of livestock in some communities (Herrero et al. 2016)	e.g., climate suitability of different cattle breeds in a changing climate (Thornton et al. 2009b; Rojas-Downing et al. 2017b)
Agroforestry			< USD5 tCO ₂ e ⁻¹ (Torres et al. 2010) Note that lack of reliable financial support	There are likely to be relatively few technological barriers (Smith et al. 2007).	institutional in some regions (e.g., seed availability; (Lillesø et al. 2011)	educational (e.g., poor knowledge of how best to integrate trees into agro-ecosystems, (Meijer et al. 2015b); lack of	susceptibility to pests (Sileshi et al. 2008)

			(Hernandez-Morcillo et al. 2018) could be a barrier.			information, (Hernandez-Morcillo et al. 2018) and cultural / behavioural (e.g., farmers perceptions, Meijer et al. 2015b)	
Agricultural diversification			Minimal (Wimmer et al. 2016) Diversification results in cost-saving and risk reduction, thus expected cost is minimal. Note that not always economically viable (Barnes et al. 2015)	technological, biophysical, educational, and cultural barriers may emerge that limit the adoption of more diverse farming systems by farmers (Barnett and Palutikof 2015; Ahmed and Stepp 2016a); Roesch-McNally et al. 2016)		technological, biophysical, educational, and cultural barriers may emerge that limit the adoption of more diverse farming systems by farmers (Barnett and Palutikof 2015; Ahmed and Stepp 2016a); Roesch-McNally et al. 2016)	technological, biophysical, educational, and cultural barriers may emerge that limit the adoption of more diverse farming systems by farmers (Barnett and Palutikof 2015; Ahmed and Stepp 2016a); Roesch-McNally et al. 2016)
Reduced grassland conversion to cropland			Minimal (Garibaldi et al. 2017) With increased demand for livestock products, it is expected that livestock has higher returns than crops. Note that avoiding conversion is low cost, but there	Since the response option involves not cultivating a current grassland, there are likely to be few biophysical or technological barriers	There could be institutional barriers in some regions (e.g., poor governance to prevent conversion)	educational (e.g., poor knowledge of the impacts of ploughing grasslands, and cultural / behavioural (e.g., strong cultural importance of crop production in some communities	Since the response option involves not cultivating a current grassland, there are likely to be few biophysical or technological barriers

			may be significant opportunity costs associated with foregone production of crops.				
Integrated water management			Minimal (Lubell et al. 2011) Integrated water management expected to reduce production costs and increase economic efficiency

Table SM6.3 Feasibility of land management response options for soils, considering cost, technological, institutional, socio-cultural and environmental and geophysical barriers and saturation and reversibility

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical
Increased soil organic carbon content			USD50 to USD170 ha ⁻¹ (FAO 2014) Based on smallholder farming - which accounts for 72% farms in the world; India farmers (medium farmers) and largescale farmers in the US (FAO 2014). The cost indicated is only for manure application and ignores other costs done under business as usual (BAU). Assumes application of 10 t ha ⁻¹ of organic	e.g., difficult to measure and verify; (Smith 2006)	Can be institutional in some regions (e.g., lack of institutional capacity; Bustamante et al. 2014c)	educational (e.g., poor knowledge of best practices among farmers; (Reichardt et al. 2009b) though cultural / behavioural barriers are likely to be small compared to other barriers (Smith et al. 2007; Wollenberg et al. 2016b)	e.g., soil type; (Baveye et al. 2018b)

			manure after every three years and minimum tillage.				
Reduced soil erosion			<p>USD50 to USD240 ha⁻¹ (Morokong et al. 2019)</p> <p>Based on prevention of soil erosion using terraces using rocks. Costs reported is only for avoided loss of carbon sequestration.</p>	Limited technology choices and technical support (Haregeweyn et al. 2015)	For instance, in Ethiopia farmers have shown an increased understanding of the soil erosion problem, but soil conservation programs face a host of barriers related to limited access to capital, limited benefits, land tenure insecurity (Haregeweyn et al. 2015)	Poor community participation (Haregeweyn et al. 2015)	
Reduced soil salinisation			<p>USD50 to USD250 ha⁻¹ (ICARDA 2012)</p> <p>For NENA region, salinity control recommended practice is deep ploughing, done once every 4 to 5 years to breakdown the hardpan subsoil. Deep ploughing costs USD200 ha⁻¹ for the four-year cycle or USD50 ha⁻¹ for each cropping season.</p>	e.g., lack of appropriate irrigation technology; (Machado and Serralheiro 2017b; CGIAR 2016; Bhattacharyya et al. 2015)	Lack of alternative irrigation infrastructure; (Evans and Sadler 2008; CGIAR 2016)	educational (poor knowledge of the causes and salinisation and how to address it; (Greene et al. 2016; Dagar et al. 2016b), and cultural / behavioural (persistence of traditional practices; (Greene et al. 2016; Dagar et al. 2016b)	e.g., lack of alternative water sources; (Bhattacharyya et al. 2015; Dagar et al. 2016b)

Reduced soil compaction			Negative cost (McLaren 2012b)	Both compaction process and remediation technologies are well-known (Antille et al. 2016b) but technological barriers exist (e.g., few decision support systems for implementation of precision management of traffic compaction)		educational (knowledge gaps; Antille et al. 2016b)	Some soils are prone to compaction (Antille et al. 2016b)
Biochar addition to soil			USD100 to USD800 tCO ₂ e ⁻¹ (McLaren 2012b) A small amount of biochar potential could be available at negative cost, and some at low cost, depending on markets for the biochar as a soil amendment (Shackley et al. 2011b; Meyer et al. 2011; Dickinson et al. 2014)	e.g., feedstock and pyrolysis temperature have large impacts on biochar properties	Can be institutional in some regions (e.g., lack of quality standards; Guo et al. 2016)	educational (e.g., low awareness among end users; Guo et al. 2016) and cultural / behavioural (Guo et al. 2016)	e.g., land available for biomass production (Woolf et al. 2010)

Table SM6.4 Feasibility of land management response options in any/other ecosystems, considering cost, technological, institutional, socio-cultural and environmental and geophysical barriers and saturation and reversibility

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical
Fire management			USD0.2 to USD6.5 billion per country per year (USA, Australia, Canada)	Technologies for fire management exist, but the cost of its implementation is relatively moderate, since it requires constant maintenance (North et al. 2015a) and can be excessive for some local communities.	e.g., lack of social or political acceptance (Freeman et al. 2017b)	educational (e.g., poor knowledge of best practices, liability issues, casualty risks and little tolerance for management errors; North et al. 2015a)	e.g., susceptibility to climate and other unpredicted events (Hurteau et al. 2014) or steep or remote areas to its application (North et al. 2015a)
Reduced landslides and natural hazards				The implementation of practices for management of landslides and natural hazards is based on engineering works and more resilient cropping systems (Noble et al. 2014; Gill and Malamud 2017b), which are often limited by their high costs, as well as biophysical, technological and educational barriers.	In the tropics, the most cited barriers for implementing landslide risk reduction measures are scientific and political in nature, and the ratio of implemented versus recommended landslide risk reduction measures is low for most landslide risk reduction components (Maes et al. 2017b).	The implementation of practices for management of landslides and natural hazards is based on engineering works and more resilient cropping systems (Noble et al. 2014; Gill and Malamud 2017b), which are often limited by their high costs, as well as biophysical, technological and educational barriers.	The implementation of practices for management of landslides and natural hazards is based on engineering works and more resilient cropping systems (Noble et al. 2014; Gill and Malamud 2017b), which are often limited by their high costs, as well as biophysical, technological and educational barriers.
Reduced pollution including			USD2 to USD13 per household	e.g., lack of technology to	e.g., poor regulation and		Since air pollution is transboundary,

acidification			(Houtven et al. 2017)	inject fertilisers below ground to prevent ammonia emissions; Shah et al., 2018	enforcement of environmental regulations; Yamineva and Romppanen, 2017		sources are often far distant from the site of impact; Begum et al., 2011
Management of invasive species / encroachment			USD500 to USD6632 per ha (Jardine et al. 2017) High cost is for California invasive alien species control; low cost from control in Massachusetts	In the case of natural enemies can be technological (Dresner et al. 2015)	Where agricultural extension and advice services are poorly developed	Education can be a barrier, where populations are unaware of the damage caused by the invasive species. Cultural / behavioural barriers are likely to be small.	Restoration programmes can take a long time (Dresner et al. 2015)
Restoration and reduced conversion of coastal wetlands			Costs for coastal wetland restoration projects vary, but they can be cost-effective at scale (Erwin 2009)		Can be institutional in some regions (e.g., poor governance of wetland use in some regions; (Lotze et al. 2006)	educational (e.g., lack of knowledge of impact of wetland conversion), though technological and cultural / behavioural barriers are likely to be small compared to other barriers.	e.g., loss of large predators, herbivores, spawning and nursery habitat; (Lotze et al. 2006)
Restoration and reduced conversion of peatlands			USD4 to USD20 tCO ₂ e ⁻¹ (McLaren 2012b)		An be institutional in some regions (e.g., lack of inputs; Bonn et al. 2014)	educational (e.g., lack of skilled labour; Bonn et al. 2014), though technological and cultural / behavioural barriers are likely to be small	e.g., site inaccessibility; Bonn et al. 2014)

						compared to other barriers.	
Biodiversity conservation			USD10 to USD50 tCO ₂ e ⁻¹ (Minx et al. 2018)

Table SM6.8 Feasibility of risk management response options, considering cost, technological, institutional, socio-cultural and environmental and geophysical barriers and saturation and reversibility

Response option	Saturation	Reversibility	Cost	Technological	Institutional	Socio-cultural	Environmental and geophysical
Management of urban sprawl			USD0.5 to USD3 trillion yr ⁻¹ globally (New Climate Economy 2018) Global cost of prevention of urban sprawl done		Barriers to policies against urban sprawl include institutional barriers to integrated land use planning and the costs to national		

			by: densification; provision of sustainable and affordable housing; and investment in shared, electric, and low-carbon transport.		governments of restricting or buying back development rights (Tan et al. 2009)	
Livelihood diversification			Barriers to diversification include the fact that poorer households and female headed households may lack assets to invest in new income streams or have a lack of education about new income sources (Berman et al. 2012b; Ahmed and Stepp 2016a; Ngigi et al. 2017)			Barriers to diversification include the fact that poorer households and female headed households may lack assets to invest in new income streams or have a lack of education about new income sources (Berman et al. 2012b; Ahmed and Stepp 2016a; Ngigi et al. 2017)
Use of local seeds						Barriers to seed sovereignty include concerns about equitability in access to seed networks and the difficulty of sustaining such projects when development donors leave (Reisman 2017b),

						and disputes over the intellectual property rights associated with seeds (Timmermann and Robaey 2016)	
Disaster risk management			Barriers to EWS include cost; an early warning system for the 80 most climate vulnerable countries in the world is estimated to cost USD 2 billion over five years to develop (Hallegatte 2012).		Institutional and governance barriers such as coordination and synchronisation among levels also effect some EWS (Birkmann et al. 2015b).		
Risk sharing instruments			USD10 to USD90 ha ⁻¹ (Schmitkey 2017) Insurance cost depends on value of crop. We use maize as an example in US (high) and Sub-Saharan Africa (low).				

1

1 **Supplementary Information for Section 6.4.3**

2 Section 6.4.3 includes tables regarding interactions for each of the 40 response options with Nature’s Contributions to People (NCP) and Sustainable
 3 Development Goals (SDG). This section includes the supporting material for those classifications.

4 **Table SM6.9 Impacts on Nature’s Contributions to People of integrated response options based on land management**

<u>Integrated response options based on land management</u>	Habitat creation and maintenance	Pollination and dispersal of seeds and other propagules	Regulation of air quality	Regulation of climate	Regulation of ocean acidification	Regulation of freshwater quantity, flow and timing	Regulation of freshwater and coastal water quality	Formation, protection and decontamination of soils and sediments	Regulation of hazards and extreme events	Regulation of organisms detrimental to humans	Energy	Food and feed	Materials and assistance	Medicinal, biochemical and genetic resources	Learning and inspiration	Physical and psychological experiences	Supporting identities	Maintenance of options	
Increased food productivity	Higher productivity spares land (e.g. Balmford et al. 2018) especially if intensification is done sustainably.	Likely may reduce native pollinators if reliant on increased chemical inputs (Potts et al. 2010) but not if through sustainable intensification.	N/A	N/A	Increased food productivity might be achieved through increased pesticide or fertiliser use, which causes runoff and dead zones in oceans (Beusen et al. 2016).	Food productivity increases could impact water quality if increases in chemicals used, but evidence is mixed on sustainable intensification (Rockström et al. 2009; Mueller et al. 2012).	Food productivity increases could impact water flow due to demand for irrigation (Rockström et al. 2009; Mueller et al. 2012).	Intensification through additional input of nitrogen fertiliser can result in negative impacts on climate, soil, water and air pollution (Tilman et al. 2002).	N/A	Increasing food production through agrochemicals may increase pest resistance over time (Tilman et al. 2002).	N/A	Sustainable intensification has potential to close yield gaps (Tilman et al. 2011).	N/A	N/A	N/A	N/A	N/A	N/A	N/A
Improved cropland management	Improved cropland management can contribute to diverse agroecosystems (Tscharntke et al. 2005) and promotes soil biodiversity (Oehl et al. 2017)	Better crop management can contribute to maintaining native pollinators (Gardiner et al. 2009).	N/A	See main text for mitigation potentials	Mitigation potential (see main text) will reduce ocean acidification.	Cropland conversion has major impacts on water quantity (Scanlon et al. 2007). Cropland management practices such as conservation tillage improve downstream water quality due to runoff (Scanlon et al. 2007).	Cropland conversion leads to poorer water quality due to runoff (Scanlon et al. 2007).	Improved cropland management has positive impacts on soils (see main text) (Kern et al. 2003).	N/A	Some forms of improved cropland management can decrease pathogens and pests (Tscharntke et al. 2016).	N/A	Conservation agriculture contributes to food productivity and reduces food insecurity (Rosegrant and Cline 2003 ; Dar & Gowda 2011; Godfrey & Garnett 2014)	N/A	N/A	N/A	N/A	N/A	Many cropping systems have cultural components (Tenberg et al. 2012).	N/A
Agriculture Improved grazing land management	Can contribute to improved habitat (Pons et al. 2003; Plantureux et al. 2005).	N/A	N/A	See main text for mitigation potentials	Mitigation potential (see main text) will reduce ocean acidification.	Likely will improve water quality (Hibbert 1983).	Likely will improve water flow (Hibbert 1983).	Improved grassland management increases soil carbon and quality (Conant et al. 2001).	N/A	N/A	N/A	Improved grassland management could contribute to food security (O'Mara 2012)	Grassland management can provide other materials (e.g. biofuel materials)	N/A	N/A	N/A	N/A	Many pastoralists have close cultural connections to livestock (Ainslie 2013)	N/A

<p>Avoidance of conversion of grassland to cropland</p>	<p>Can preserve natural habitat (Peeters, 2009)</p>	<p>N/A</p>	<p>N/A</p>	<p>See main text for mitigation potentials</p>	<p>Mitigation potential (see main text) will reduce ocean acidification.</p>	<p>Will likely improve water quality (inferred from improved soil quality in Saziozzi et al., 2001)</p>	<p>Will likely improve water flow (inferred from improved soil quality in Saziozzi et al., 2001)</p>	<p>Will improve soil quality (Saziozzi et al., 2001)</p>	<p>N/A</p>	<p>Diverse agroecosystems tend to have less detrimental impacts from pests (Gardiner et al 2009; Altieri & Letourneau 1982)</p>	<p>N/A</p>	<p>Reducing cropland conversion can reduce food production (West et al. 2010).</p>	<p>N/A</p>	<p>N/A</p>	<p>N/A</p>	<p>N/A</p>	<p>Retaining natural ecosystems can preserve genetic diversity (Ekins et al., 2003).</p>
<p>Integrated water management</p>	<p>Ecosystem health and services can be enhanced by improving water management (Boelee E and E 2011). Securing ecosystem (Lloyd et al. 2013), integrated ecosystem-based management into water resources planning and management, linking ecosystem services and water security (Nicole Bernex 2016), improving correlation between amount of water resources and supply ecosystem services, combining water resources management and supply of ecosystem services (Liu et al. 2016).</p>	<p>Some integrated water management strategies generate synergies between multiple ecosystem services, such as pollination, farm profitability (Hipólito et al, 2018).</p>	<p>IWM practices exert strong influence on ecosystem structure and function, with potentially large implications for regulating air quality (Xia et al., 2017; Hardiman et al, 2019).</p>	<p>IWM supports favourable forests conditions thereby influencing the storage and flow of water in watersheds (Eisenbies et al. 2007) which are important for regulating microclimates (Pierzynski et al., 2017).</p>	<p>N/A</p>	<p>Improving regulations for water sharing, trading and pricing (ADB 2016), water smart appliance, water smart landscapes (Dawadi and Ahmad 2013), common and unconventional water sources in use (Rengasamy 2006) will increase water quantity.</p>	<p>Improving regulation to prevent aquifer and surface water depletion, controlling over water extraction, improvement of water management and management of landslides and natural hazards. Watering shifting sand dunes (sprinkler), water resources conservation (Nejad 2013; Pereira 2002a), enhancing rainwater management, reducing recharge and increasing water use in discharge areas (DERM 2011).</p>	<p>IWM provide co-benefits such as healthier soils, more resilient and productive ecosystems (Grey and Sadoff 2007; Liu et al. 2017; Scott et al. 2011)</p>	<p>Change in water availability through improving co-managing floods and groundwater depletion at the river basin such as Managed Aquifer Recharge (MAR), Underground Taming of Floods for Irrigation (UTFI), restore over-allocated or brackish groundwater dependent ecosystems protection, reducing evaporation losses are significantly contributed to response climate change and reduced impacts of extreme weather event in desertification areas (Dillon and Arshad 2016b).</p>	<p>IWM can support the production of biomass for energy and firewood (Mbow et al., 2014).</p>	<p>Increasing demand for food, fiber and feed will put great strains on land, water, energy and other resources (WBCSD, 2014). Water conservation and balance in the use of natural resources enforcement (based water resources, water conservation measures, water allocations) (Ward et al. 2008) are good options to response climate change and nature's prevention.</p>	<p>IWM supports favourable forests conditions thereby providing wood and fodder and other materials (Locate Ili et al. 2015a). However, conservation restrictions on the storage and flow of water in watersheds (Eisenbies et al. 2007) can restrict the access to resources (e.g. firewood).</p>					

<p>Forests</p>	<p>Forest management and forest restoration</p>	<p>Forest landscape restoration specifically aims to regain ecological integrity and enhance human well-being in deforested or degraded forest landscape (Maginnis and Jackson 2007; Stanturf et al. 2014). For example, facilitating tree species mixture means storing at least as much carbon as monocultures while enhancing biodiversity (Hulvey et al. 2013). Selective logging techniques are “middle way” between deforestation and total protection, allowing to retain substantial levels of biodiversity, carbon, and timber stocks (Putz et al. 2012),</p>	<p>Likely contributes to native pollinators (Kremen et al. 2007)</p>	<p>Trees remove air pollution by the interception of particulate matter on plant surfaces and the absorption of gaseous pollutants through the leaf stomata. Computer simulations with local environmental data reveal that trees and forests in the conterminous United States removed 17.4 million tonnes (t) of air pollution in 2010 (range: 9.0–23.2 million t), with human health effects valued at 6.8 billion U.S. dollars (range: USD1.5–13.0 billion) (Novak et al., 2014)</p>	<p>See main text for mitigation potentials</p>	<p>Mitigation potential (see main text) will reduce ocean acidification.</p>	<p>Forest cover can stabilise intense runoff during storms and flood events (Locatelli et al. 2015a). Mangroves can protect coastal zones from extreme events (hurricanes) or sea level rise. However, forests also can have adverse side-effects for reduction of water yield and water availability for human consumption (Bryan and Crossman 2013).</p>	<p>Forests tend to maintain water quality by reducing runoff and trapping sediments and nutrients (Idris Medugu et al. 2010a; Salvati et al. 2014). Precipitation filtered through forested catchments delivers purified ground and surface water (co-benefits) (Calder 2005; Ellison et al. 2017; Neary et al. 2009).</p>	<p>Forests counteract wind-driven degradation of soils, and contribute to soil erosion protection and soil fertility enhancement for agricultural resilience (Locatelli et al. 2015a).</p>	<p>Forest cover can stabilise land against catastrophic movements associated with wave action and intense runoff during storms and flood events (Locatelli et al. 2015a). Reducing harvesting rates and prolonging rotation periods may induce an increased vulnerability of stands to external disturbances and catastrophic events (Yousefpour et al. 2018). Forest management strategies may decrease stand-level structural complexity and may make forest ecosystems more susceptible to natural disasters like wind throws, fires, and diseases (Seidl et al. 2014).</p>	<p>Forests can contribute to weed and pest control and landscape diversity generally improves opportunities for biological pest control (Gardiner et al. 2009)</p>	<p>SFM may increase availability of biomass for energy (Kraxner et al 2003; Sikkema et al 2014)</p>	<p>The proximity of forest to cropland constitutes a threat to livelihoods in terms of crop raiding by wild animals and in constraints in availability of land for farming (Few et al. 2017). The competition for land between afforestation/reforestation and agricultural production is a potentially large adverse side-effect (Boysen et al. 2017a,b; Kreidenweis et al. 2016; Smith et al. 2013). An increase in global forest area can lead to increases in food prices through increasing land competition (Calvin et al. 2014; Kreidenweis et al. 2016; Reilly et al. 2012; Smith et al. 2013; Wise et al. 2009).</p>	<p>Forests provide wood and fodder and other materials (Locatelli et al. 2015a). However, conservation restrictions to preserve ecosystem integrity can restrict the access to resources (e.g. firewood).</p>	<p>Can provide medicinal and other resources.</p>	<p>Natural ecosystems often inspire learning (Turtle et al., 2015)</p>	<p>Forest landscape restoration specifically aims to enhance human well-being (Maginnis and Jackson 2007; Stanturf et al. 2014). Afforestation/reforestation and avoided deforestation benefit biodiversity and species richness, and generally improve the cultural and recreational value of ecosystems (co-benefits) (Knoke et al. 2014).</p>	<p>Many forest landscapes have cultural ecosystem services components (Plieninger et al. 2015)</p>	<p>Retaining natural ecosystems can preserve genetic diversity (Ekins et al., 2003).</p>

		2016; Ellison et al. 2017).											Smith et al. 2013). An increase in global forest area can lead to increases in food prices through increasing land competition (Calvin et al. 2014; Kreidenweis et al. 2016; Reilly et al. 2012; Smith et al. 2013; Wise et al. 2009).	d).					
	Afforestation	Forest landscape restoration specifically aims to regain ecological integrity and enhance human well-being in deforested or degraded forest landscape (Maginnis and Jackson 2007; Stanturf et al. 2014). In the case of afforestation, simply changing the use of land to planted forests is not sufficient to increase abundance of indigenous species, as they depend on type of vegetation, scale of the land transition, and time required for a population to establish (Barry et al. 2014).	N/a	N/A	See main text for mitigation potentials	Mitigation potential (see main text) will reduce ocean acidification.	Depends on where reforestation and with what species (Scott et al. 2005). Trees enhance soil infiltration and, under suitable conditions, improve groundwater recharge (Calder 2005; Ellison et al. 2017; Neary et al. 2009).	Afforestation using some exotic species can upset the balance of evapotranspiration regimes, with negative impacts on water availability particularly in arid regions (Ellison et al. 2017; Locatelli et al. 2015a; Trabucco et al. 2008). Afforestation in arid and semiarid regions using species that have evapotranspiration rates exceeding the regional precipitation may aggravate the groundwater decline (Locatelli et al. 2015a; Lu et al. 2016). Changes in runoff affect water supply but can also contribute to changes in flood risks, and irrigation of forest plantations can increase water consumption (Sterling et al. 2013).	Afforestation and reforestation options are frequently used to counteract land degradation problems (Yirdaw et al. 2017), whereas when they are established on degraded lands they are instrumental to preserve natural forests (co-benefit) (Buongiorno and Zhu 2014). Afforestation runs the risk of decreasing soil nutrients, especially in intensively managed plantations; in one study, afforestation sites had lower soil P and N content (Berthrong et al. 2009).	Some afforestation may make forest ecosystems more susceptible to natural disasters like wind throws, fires, and diseases (Seidl et al. 2014).	N/A	Afforestation may increase availability of biomass for energy use (Obersteiner et al. 2006)	Future needs for food production are a constraint for large-scale afforestation plans (Locatelli et al. 2015a). Global food crop demand is expected by 50%-97% between 2005 and 2050 (Valin et al. 2014). Future carbon prices will facilitate deployment of afforestation projects at expenses of food availability (adverse side-effect), but more liberalised trade in agricultural commodities could buffer food price increases following afforestation in tropical regions (Kreidenweis et al. 2016).	Could increase availability of biomass (Griscom et al., 2017)	N/A	N/A	Green spaces support psychological wellbeing (Coldwell & Evans, 2018)	Afforestation/ reforestation can increase areas available for recreation and tourism opportunities (Knoke et al. 2014).	N/A
Soils	Increased soil organic carbon content	Improving soil carbon can increase overall resilience of	N/A	N/A	See main text for mitigation potentials	Rivers transport dissolved organic	Soil organic matter is known to increase water	Soil organic matter is known to increase water filtration and	Increasing SOM contributes to healthy soils (Lehmann &	N/A	Increased SOM decreases pathogens in soil (Lehmann	N/A	Lal 2006 notes that "Food-grain production in	In terms of raw material	In terms of raw materials, numerous	N/A	N/A	N/A	N/A

	landscapes (Tscharnke et al. 2005)				matter to oceans (Hedges et al 1997), but unclear if improved SOM will decrease this and by how much.	filtration and can regulate downstream flows (Keesstra et al., 2016)	protects water quality (Lehmann & Kleber 2015)	Kleber 2015)		& Kleber 2015)		developing countries can be increased by 24–39 (32+/-11) million Mgy-1 through improving soil quality by increasing the SOC pool and reversing degradation processes".	s, numerous products (e.g. pharmaceuticals, clay for bricks and ceramics, silicon for bricks and electronics, and other minerals; SSSA, 2015) are provided by soils.					
Reduced soil erosion	Managing soil erosion decreases need for expanded cropland into habitats (Pimental et al 1995)	N/A	Particulate matter pollution, a main consequence of wind erosion, imposes severe adverse impacts on materials, structures and climate which directly affect the sustainability of urban cities (Al-Thani et al. 2018)	N/A	N/A	Managing soil erosion improves water quality (Pimental et al 1995)	Managing soil erosion improves water flow (Pimental et al 1995)	Will improve soil quality (Keesstra et al., 2016)	Reducing soil erosion reduces vulnerability to hazards like wind storms in dryland areas and landslides in mountainous areas (EL-Swify 1997)	N/A	N/A	Managing erosion can lead to increased food production on croplands; however, other forms of management (revegetation, zero tillage) might reduce land available for food.	N/A	N/A	N/A	N/A	N/A	N/A
Reduced soil salinisation	Salinisation decreases soil microbial diversity (Nie et al. 2009)	N/A	N/A	N/A	N/A	N/A	Management of soil salinity improves water quality (Kotb et al. 2000; Zalidis et al 2002; Soane & Ouwerkerk 1995)	Will improve soil quality (Keesstra et al., 2016)	N/A	N/A	N/A	Reversing degradation contributes to food productivity and reduces food insecurity (Pimental et al. 1995; Shiferaw & Holden 1999).	N/A	N/A	N/A	N/A	N/A	N/A

	Reduced soil compaction	Preventing compaction can reduce need to expand croplands (Lal, 2001).	N/A	N/A	N/A	N/A	Compaction can increase water runoff (Soane & Ouwerkerk 1995). Management of soil compaction improves water quality and quantity (Soane & van Ouwerkerk 1995; Zalidis et al 2002)	Management of soil compaction improves water quality and quantity (Soane & van Ouwerkerk 1995; Zalidis et al 2002)	Will improve soil quality (Keesstra et al., 2016)	Compaction in soils increases rates of runoff and can contribute to floods (Hümann et al 2011)	N/A	N/A	Compactions reduces agricultural productivity and thus contributes to food insecurity (Navaz et al 2013)	N/A	N/A	N/A	N/A	N/A	N/A
	Biochar addition to soil	N/A	N/A	N/A	See main text for mitigation potentials	Mitigation potential (see main text) will reduce ocean acidification.	Biochar improves soil water filtration and retention (Spokas et al 2011; Beck et al. 2011)	Biochar improves soil water filtration and retention (Spokas et al 2011; Beck et al. 2011)	Can improve soil quality (Sohi, 2012)	N/A	N/A	N/A	Contributes to increased food production (Smith 2016; Jeffery et al., 2017)	N/A	N/A	N/A	N/A	N/A	N/A
Other ecosystems	Fire management	Proactive fire management can improve natural habitat (Burrows 2008).	Reducing fire risk can improve habitat for pollinators (Brown et al. 2017)	Fire management improves air quality particularly in the periurban interface (Bowman et al. 2005)	See main text for mitigation potentials	Mitigation potential (see main text) will reduce ocean acidification.	Fires affect water quality and flow due to erosion exposure (Townsend & Douglas 2000).	Fires affect water quality and flow due to erosion exposure (Townsend & Douglas 2000).	Fire cause damage to soils, therefore fire management can improve them (Certini 2005)	Will reduce risk of wildfires as a hazard (McCaffrey 2002)	Landscape diversity generally improves opportunities for biological pest control (Gardiner et al. 2009)	Will increase availability of biomass, as fuel removal is a key management strategy (Becker et al. 2009)	N/A	N/A	N/A	N/A	Reduced wildlife risk will increase recreation opportunities in landscapes (Venn & Calkin 2011).	N/A	Retaining natural ecosystems can preserve genetic diversity (Ekins et al., 2003).
	Reduced landslides and natural hazards	Can preserve natural habitat (Dolidon et al. 2009)	N/A	N/A	N/A	N/A	Likely will improve water quality (Dolidon et al. 2009)	Likely will improve water flow (Dolidon et al. 2009)	Will improve soil quality (Keesstra et al., 2016)	Will reduce risk of disasters (Dolidon et al. 2009; Kausky 2010)	N/A	N/A	Landslides are one of the natural disasters that have impacts on food security (de Haen & Henrich 2007)	N/A	N/A	N/A	N/A	N/A	N/A
	Reduced pollution including acidification	Air pollution like acid rain has major impacts on habitats like lakes (Schindler et al 1989)	Pollution interferes with scents, which impact pollinators ability to detect resources (McFredrick et al 2008)	Will improve air quality with public health benefits (Nemet et al. 2010)	See main text for mitigation potentials	N/A	N/A	Pollution increases acidity of surface water, with likely ecological effects (Larsen et al 1999)	Soil acidification due to air pollution in a serious problem in many countries (Zhou et al. 2013)	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A

<p>Management of invasive species / encroachment</p>	<p>Improved management of IAS can lead to improved habitat and ecosystems (Richardson & van Wilgen 2004).</p>	<p>Invasive species can disrupt native plant-pollinator relations (Ghazoul 2006)</p>	<p>N/A</p>	<p>N/A</p>	<p>N/A</p>	<p>Many invasives can reduce water flow (Richardson & Van Wilgen 2004).</p>	<p>Invasive species can reduce water quality (Burnett et al. 2007; Chamier et al. 2012)</p>	<p>Likely to improve soil as invasive species generally have negative effects (Ehrenfeld & Scott 2001).</p>	<p>N/A</p>	<p>Many IAS are harmful pests (Charles & Dukes 2008).</p>	<p>N/A</p>	<p>IAS can compete with crops and reduce crop yields by billions of dollars annually (Pejchar & Mooney 2009)</p>	<p>Many invasives are important suppliers of materials (Pejchar & Mooney 2009).</p>	<p>N/A</p>	<p>N/A</p>	<p>N/A</p>	<p>N/A</p>	<p>Reducing invasives can increase biological diversity of native organisms (Simberloff 2005)</p>

<p>Restoration and avoided conversion of peatlands</p>	<p>Will preserve natural habitat (Griscom et al., 2017)</p>	<p>Could promote natural pollinators (Seddon et al., 2016)</p>	<p>N/A</p>	<p>See main text for mitigation potentials</p>	<p>Mitigation potential (see main text) will reduce ocean acidification.</p>	<p>Peatland restoration will improve water quality as they play important roles in water retention and drainage (Johnston 1991).</p>	<p>Peatland restoration will improve water quality as they play important roles in water retention and drainage (Johnston 1991).</p>	<p>Will improve soil quality (Griscom et al., 2017)</p>	<p>N/A</p>	<p>Landscape diversity generally improves opportunities for biological pest control (Gardiner et al. 2009)</p>	<p>Will reduce supply of any biomass or energy sourced from peatlands (Pin Koh 2007)</p>	<p>May reduce land available for smallholders in tropical peatlands (Jewitt et al 2014)</p>	<p>Will reduce supply of some materials sourced from peatlands (e.g palm oil, timber) (Murdiyarso et al. 2010)</p>	<p>Natural ecosystems are often source of medicines (UNEP, 2016)</p>	<p>Natural ecosystems often inspire learning (Turtle et al., 2015)</p>	<p>Natural environments support psychological wellbeing (Coldwell & Evans, 2018)</p>	<p>Natural environments support psychological wellbeing (Coldwell & Evans, 2018)</p>	<p>Retaining natural ecosystems can preserve genetic diversity (Ekins et al., 2003).</p>

	<p>Biodiversity conservation</p>	<p>Biodiversity conservation includes measures aiming to promote species richness and natural habitats, and to maintain them through protected areas (Cromsigt et al., 2018).</p>	<p>Reduced or absent populations of seed-dispersing animals result in poor to no dispersal, especially of large-seeded trees that depend on large animals such as elephants (Anzures-Dadde et al. 2011; Brodie and Aslan 2012; Beaune et al. 2013; Brockerhoff et al. 2017). Animal pollination, which is fundamental to the reproduction and persistence of most flowering plants, is an important ecosystem service (Millennium Ecosystem Assessment 2005). As biodiversity contributes to various ecosystem processes, functions and services, the declining diversity and abundance of pollinators (mainly insects and birds) has raised concerns about the effects on both wild and crop plants (Potts et al. 2010).</p>	<p>Trees in the landscape ensured by protected areas can remove air pollutants (Sutton et al., 2007)</p>	<p>See main text for mitigation potentials</p>		<p>Many actions taken to increase biodiversity (eg protected areas) can also have incidental effects of improving water quantity (Egoh et al. 2009)</p>	<p>Many actions taken to increase biodiversity (eg protected areas) can also have incidental effects of improving water quality (Egoh et al. 2009)</p>	<p>Management of wild animals and protected habitats can influence soil conditions via changes in fire frequency (as grazers lower grass and vegetation densities as potential fuels) and nutrient cycling and transport (by adding nutrients to soils). Conserving and restoring megafauna in northern regions also prevents thawing of permafrost. Management of wild animals can influence land degradation processes by grazing, trampling and compacting soil surfaces, thereby altering surface temperatures and chemical reactions affecting sediment and carbon retention. (Cromsigt et al., 2018; Schmitz et al., 2018)</p>	<p>Management of wild animals can influence fire frequency as grazers lower grass and vegetation densities as potential fuels (Schmitz et al., 2014).</p>			<p>Regulation of wild animals affects food for hunting and availability of potential feed for livestock (Cromsigt et al., 2018).</p>		<p>Source of medicines (UNEP, 2016)</p>	<p>Natural ecosystems often inspire learning (Turtle et al., 2015)</p>	<p>indigenous peoples commonly link forest landscapes and biodiversity to tribal identities, association with place, kinship ties, customs and protocols, stories, and songs (Gould et al. 2014; Lyver et al. 2017a, b).</p>	<p>Retaining natural ecosystems can preserve genetic diversity (Ekins et al., 2003).</p>
--	---	---	---	--	--	--	---	--	--	---	--	--	--	--	---	--	--	--

	Enhanced weathering of minerals	N/A	N/A	N/A	See main text for mitigation potentials	Addition of basic minerals counteracts ocean acidification (Taylor et al., 2016)	N/A	May have negative effects on water quality (Atekwane et al. 2005)	Could improve soil quality (Rau & Caldiera 1999; Kantola et al 2017)	N/A	N/A	N/A	Can contribute to increase food production by replenishing plant available silicon, potassium and other plant nutrients (Beerling et al., 2018)	N/A	N/A	N/A	N/A	N/a	N/A
Carbon dioxide removal	Bioenergy and BECCS	Likely will reduce natural habitat with negative effects on biodiversity (Hof et al. 2018)	Would reduce natural pollinators due to decreased natural habitat if in competition (Keitt 2009).	The use of BECCS could reduce air pollution (SR15)	See main text for mitigation potentials	Mitigation potential (see main text) will reduce ocean acidification.	Will likely require water for plantations of fast growing trees and models show high risk of water scarcity if BECCS is deployed on widespread scale (Popp et al 2011; Smith et al. 2016; Hejazi et al., 2014) through both increases in water withdrawals (Hejazi et al., 2014; Bonsch et al., 2015) and changes in surface runoff (Cibin et al., 2015)	Bioenergy can affect freshwater quality via changes in nitrogen runoff from fertiliser application. However, the sign of the effect depends on what would have happened absent any bioenergy production, with some studies indicating improvements in water quality (Ng et al., 2010) and others showing declines (Sinha et al., 2019)	Will likely decrease soil quality if exotic fast growing trees used (Stoy et al. 2018)	N/A	N/A	BECCS and biofuels can contribute up to 300 EJ of primary energy by 2100 (Clarke et al., 2014).	BECCS will likely lead to significant trade-offs with food production (Smith et al 2016; Popp et al., 2017; Fujimori et al., in review)	N/A	N/A	N/A	BECCS would drive land use conversion and reduce opportunities for recreation/tourism.	BECCS would drive land use conversion and reduce culturally significant landscapes.	BECCS would drive land use conversion and reduce genetic diversity.

Table SM6.11 Impacts on Nature’s Contributions to People of integrated response options based on risk management

<u>Integrated response options based on risk management</u>	Habitat creation and maintenance	Pollination and dispersal of seeds and other propagules	Regulation of air quality	Regulation of climate	Regulation of ocean acidification	Regulation of freshwater quantity, flow and timing	Regulation of freshwater and coastal water quality	Formation, protection and decontamination of soils and sediments	Regulation of hazards and extreme events	Regulation of organisms detrimental to humans	Energy	Food and feed	Materials and assistance	Medicinal, biochemical and genetic resources	Learning and inspiration	Physical and psychological experiences	Supporting identities	Maintenance of options	
Management of urban sprawl	Reducing urban sprawl can help preserve natural habitat in periurban areas (Pataki et al 2011)	Reducing urban sprawl will help reduce loss of natural pollinators from habitat conversion (Cane 2005)	Urban sprawl is a major contributor to air pollution (Frumkin 2002)	See main text on climate mitigation impacts		Managing urban sprawl can increase water availability (Pataki et al 2011)	Urban sprawl is associated with higher levels of water pollution due to loss of filtering vegetation and increasing impervious surfaces (Romero & Ordenes 2004; Tu et al 2007; Pataki et al 2011)	Likely to be beneficial for soils as soil sealing is major problem in urban areas (Scalenghe & Marsan 2009)	N/A	N/A		Urban sprawl often competes with land for food production and can reduce overall yields (Chen 2007, Barbero-Sierra et al., 2013)	N/A	N/A	N/A	N/A	N/A	N/A	N/A

Livelihood diversification	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	Diversification is associated with increased access to income and additional food sources for the household (Pretty et al. 2003)	Diversification can increase access to materials (Smith et al. 2017)	N/A	N/A	N/A	N/A	N/A
Use of local seeds	Use of commercial seeds can contribute to habitat loss (Upreti & Upreti 2002)	Use of open pollinated seeds is beneficial for pollinators and creates political will to conserve them (Helicke 2015)	N/A	N/A	N/A	Local seeds often have lower water demands, as well as less use of pesticides that can contaminate water (Adhikari 2014)	Likely to contribute to less pollution as local seeds are usually grown organically (Adhikari 2014)	Likely to contribute to better soils as local seeds are usually grown organically (Adhikari 2014)	N/A	Local seeds often need less pesticides thereby reducing pest resistance (Adhikari 2014)	N/A	Local seeds can lead to more diverse and healthy food in areas with strong food sovereignty networks (Coomes et al. 2015; Bisht et al. 2018). However local seeds often are less productive than improved varieties.		Many local seeds can have multiple functions, including medicinals (Hammer & Teklu 2008)	Passing on seed information is important cultural learning process (Coomes et al. 2015)		Seeds associated with specific cultural identities for many (Coomes et al. 2015)	Food sovereignty movements have promoted saving of genetic diversity of crops through on-farm maintenance (Isakson 2009)
Disaster risk management	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	DRM helps people avoid extreme events and adapt to climate change (Mechler et al. 2014)	N/A	N/A	Famine early warning systems have been successful in Sahelian Africa to alert authorities to impending food shortages so that food acquisition and transportation from outside the region can begin, potentially helping millions of people (Genesio et al. 2011; Hillbruner and Moloney 2012)						N/A

		Commercial crop insurance often encourages habitat conversion; Wright and Wimberly (2013) found a 531,000 ha decline in grasslands in the Upper Midwest of the US 2006-2010 due to crop conversion driven by higher prices and access to insurance.	Crop insurance is likely to impact natural pollinators due to incentives for production (Horowitz & Lichtenberg 1993)	N/A	N/A	N/A	N/A	Likely to have negative effect as crop insurance encourages more pesticide use (Horowitz & Lichtenberg 1993).	One study found a 1% increase in farm receipts generated from subsidised farm programs (including crop insurance and others) increased soil erosion by 0.135 tons per acre (Goodwin and Smith 2003).	N/A	Crop insurance increases nitrogen use and leads to treating more acreage with both herbicides and insecticides (Horowitz & Lichtenberg 1993)	N/A	Crop insurance has generally lead to (modest) expansions in cultivated land area and increased food production (Claassen et al. 2011; Goodwin et al. 2004)	Insurance encourages monocropping leading to loss of genetic diversity for future (Glauber 2004)	N/A	N/A	N/A	Insurance encourages monocropping leading to loss of genetic diversity for future (Glauber 2004)

Table SM6.12 Impacts on the UN SDG of integrated response options based on land management

<u>Integrated response options based on land management</u>	GOAL 1: No Poverty	GOAL 2: Zero Hunger	GOAL 3: Good Health and Well-being	GOAL 4: Quality Education	GOAL 5: Gender Equality	GOAL 6: Clean Water and Sanitation	GOAL 7: Affordable and Clean Energy	GOAL 8: Decent Work and Economic Growth	GOAL 9: Industry, Innovation and Infrastructure	GOAL 10: Reduced Inequality	GOAL 11: Sustainable Cities and Communities	GOAL 12: Responsible Consumption and Production	GOAL 13: Climate Action	GOAL 14: Life Below Water	GOAL 15: Life on Land	GOAL 16: Peace and Justice Strong Institutions	GOAL 17: Partnerships to achieve the Goal
Agriculture Increased food productivity	Increasing farm yields for smallholders contributes to poverty reduction (Irz et al 2001; Pretty et al 2003)	Increasing farm yields for smallholders reduces food insecurity (Irz et al 2001; Pretty et al 2003).	Increased food productivity leads to better health status (Rosegrant & Cline 2003; Dar & Gowda 2011)	N/A	Increased productivity can benefit female farmers, who make up 50% of agricultural labor in sub-Saharan Africa (Ross et al 2015)	Food productivity increases could impact water quality if increases in chemicals used, but evidence is mixed on sustainable intensification (Rockstrom et al 2009; Mueller et al 2012).	N/A	Increased agricultural production generally (Lal 2006) contributes to increased economic growth.	N/A	Increased agricultural production can contribute to reducing inequality among smallholders (Datt & Ravallion 1998).	Increased food production can increase urban food security (Ellis & Sumberg 1998).	N/A	See main text on climate mitigation and adaptation	Increased food productivity might be achieved through increased pesticide or fertiliser use, which causes runoff and dead zones in oceans (Beusen et al 2016)	See main text on desertification and degradation	N/A	Improved agricultural productivity generally correlates with increases in trade in agricultural goods (Fader et al. 2013)

		et al. 2012).	al. 2012).				Improved livestock management can contribute to better water quality such as through manure management (Herrero & Thornton 2013)		global South (Mack 1990)				(de Wit et al 1995).					
Agro-forestry	Agroforestry can be usefully used for poverty reduction (Leakey & Simons 1997).	Agroforestry contributes to food productivity and reduces food insecurity (Mbow et al. 2014).	Agroforestry positively contributes to food productivity and nutritious diets (Haddad 2000)	N/A	Increased use of agroforestry can benefit female farmers as it requires low overhead, but land tenure issues must be paid attention to (Kiptot & Franzel 2012).	Agroforestry can be used to increase ecosystem services benefits, such as water quantity and quality (Jose 2009)	Agroforestry could increase biomass for energy (Mbow et al. 2014)	Agroforestry and other forms of employment in forest management make major contributions to global GDP (Pimental et al 1997).	N/A	Agroforestry promotion can contribute to reducing inequality among smallholders (Lefmeister et al 2018).	N/A		Agroforestry contributes to sustainable production goals (Mbow et al 2014).	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
Agricultural diversification	Agricultural diversification is associated with increased welfare and incomes and decreased levels of poverty in several country studies (Arslan et al. 2018; Asfaw et al. 2018; Weinberger & Lumpkin 2007).	Diversification is associated with increased access to income and additional food sources for the farming household (Pretty et al. 2003; Ebert 2014). Diversification can also reduce the risk of crop pathogens spreading across landscapes (Lin 2011).	More diversified agriculture leads to diversified diets which have better health outcomes (Block & Webb 2001; Ebert 2014; Kadiyala et al 2014) particularly for women and children (Pretty et al. 2003)	N/A	N/A	N/A	N/A	Agricultural diversification can lead to economic growth (Rahman 2009; Pingali & Rosegrant 1995). It allows farmers to choose a strategy that both increases resilience and provides economic benefits, including functional biodiversity at multiple spatial and/or temporal scales, through practices developed via	N/A	Increased agricultural diversification can contribute to reducing inequality among smallholders (Makate et al 2016), although there is mixed evidence of inequality also increasing in commercialised systems (Pingali & Rosegrant 1995; Weinberger & Lumpkin 2007)	N/A	N/A	N/A	See main text on desertification and degradation	N/A	N/A	N/A	

								traditional and/or agroecological scientific knowledge (Lin 2011 ; Kremen et al. 2012).									
Avoidance of conversion of grassland to cropland	May reduce land available for cropping or livestock for poorer farmers ; some grassland restoration programs in China have been detrimental to poor pastoralists (Foggin 2008)	Can affect food security when competition for land occurs (O'Mara 2012)	N/A	N/A	N/A	Retaining grasslands contributes to better water retention and improved quality (Scanlon et al 2007).	N/A	Reduced cropland expansion may decrease GDP (Lewandrowski et al 1999)	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
Integrated water management	Green water harvesting contributes to alleviate poverty in Sub-Saharan Africa (Rockström and Falkenmark 2015). Improving water irrigation (Rengasamy 2006), improving rainfed agriculture (integrating soil and water management, rainfall infiltration and water harvesting, provides a large co-benefit to delivery of food security and poverty reduction (UNCTAD 2011)	Integrated, efficient, equitable and sustainable water resource management (as water for agroecosystem) plays importance for food production and benefits to people (Lloyd et al. 2013).	Water is a finite and irreplaceable resource that is fundamental to human well-being. It is only renewable if well managed. Integrated water management is vital option for reducing the global burden of disease and improving the health, welfare and productivity of populations. Today, more than 1.7 billion people live in river basins where depletion through use exceeds natural recharge, a trend that	N/A	Involving both women and men in integrated water resources initiatives can increase project effectiveness and efficiency (Green & Baden 1995)	Water resource management is intended to solve watershed problems on a sustainable basis, and these problems can be categorised into lack of water (quantity), deterioration in water quality, ecological effects, poor public participation, and low output economic value for investment in watershed-related activities (Lee et al. 2018). Integrated water management, increase	N/A	Water is at the core of sustainable development and is critical for socio-economic development, healthy ecosystems and for human survival itself. Integrated water management can play a key enabling role in strengthening the resilience of social, economic and environmental systems in the light of rapid and unpredictable changes	N/A	IWM can increase access of industry to water for economic growth (Rahman & Varis 2005)	Water is a limiting factor in urban growth and IWM can help improve access to urban water supplies (Bao & Fang 2012)	Poor sectoral coordination and institutional fragmentation have triggered an unsustainable use of resources and threatened the long-term sustainability of food, water, and energy security (Rassul 2016).	See main text on climate mitigation and adaptation	IWM on land is likely to improve water quality runoff into oceans (Agboola & Braimah 2009)	See main text on desertification and degradation	Integrated water management, increase water-use efficiency across all sectors and ensure sustainable withdrawals and supply of freshwater to address water scarcity, and substantially reduce the number of people suffering from water scarcity (UN Water, 2015).	

				will see two-thirds of the world's population living in water-stressed countries by 2025 (UNWater 2015)			water-use efficiency across all sectors and ensure sustainable withdrawals and supply of freshwater to address water scarcity, and substantially reduce the number of people suffering from water scarcity (UNWater 2015).		(UN Water, 2015).									
Forestry	Forest management and forest restoration	May contribute to poverty reduction if conditions are right (Blomley & Ramadhani 2006; Donovan et al 2006), but conflicting data, as it may also favor large landowners who are less poor (Rametsteiner and Simula 2003).	Forest expansion can affect crop production when competition for land occurs (Angelsen 2010). An increase in global forest area can lead to increases in food prices through increasing land competition (Calvin et al. 2014b; Kreidenweis et al. 2016c; Reilly et al. 2012b; Smith et al. 2013a; Wise et al. 2009b)	N/A	N/A	Women face challenges in sustainable forest management (Mwangi et al 2011), but N/A how SFM affects gender equity.	Forests tend to maintain water quality by reducing runoff and trapping sediments and nutrients (Idris Medugu et al. 2010c; Salvati et al. 2014a). Due to evapotranspiration, trees recharge atmospheric moisture, contributing to rainfall locally and in distant location, and trees' microbial flora and biogenic volatile organic compounds can directly promote rainfall (Arneeth et al. 2010). Trees enhance soil infiltration and, under	SFM may increase availability of biomass for energy (Kraxner et al. 2013; Sikkema et al. 2013)	Forest management often require employment for active replanting, etc. (Ros-Tonen et al 2008)	Forestry supplies wood for industrial use (Gustavsson & Sathre 2011)	N/A	Community forest management can contribute to stronger communities (Padgee et al 2006)	Improved forest management contributes to sustainable production goals, e.g. thru certification of timber (Ramets teiner and Simula 2003).	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	Sustainable forest management often requires collective action institutions (Ros-Tonen et al 2008).	Sustainable forest management can contribute to increases in demand for wood products (e.g. certification) (McDonald & Lane 2004)

		participants					microbial flora and biogenic volatile organic compounds can directly promote rainfall (Armeth et al. 2010). Trees enhance soil infiltration and, under suitable conditions, improve groundwater recharge (Calder 2005; Ellison et al. 2017a; Neary et al. 2009b).											
		May contribute to poverty reduction but conflicting data (Tschakert 2007). Many projects for reforestation may have some small impacts on poor households, while others actually increased poverty due to land losses or lack of economic impacts (Jindal et al 2008).	Forest expansion can affect crop production when competition for land occurs (Angelsen 2010). An increase in global forest area can lead to increases in food prices through increasing land competition (Calvin et al. 2014b; Kreidenweis et al. 2016c; Reilly et al. 2012b; Smith et al. 2013a; Wise et al. 2009b)	Reforestation can enhance human well-being by microclimatic regulation for protecting people from heat stresses (Locatelli et al. 2015c) and generally improve the cultural and recreational value of ecosystems (Knoke et al. 2014). Trends of forest resources of nations are found to positively correlate with UNDP Human Development Index (Kauppi et al. 2018).	N/A	N/A	Particular activities associated with forest landscape restoration, such as mixed planting, assisted natural regeneration, and reducing impact of disturbances (e.g. prescribed burning) have positive implications for fresh water supply (Ciccarese et al. 2012; Suding et al. 2015).	Reforestation can increase availability of biomass for energy use (Swischer 1994).	Reforestation often require employment for active replanting, etc. (Jindal et al. 2008)	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
		Although some have argued that afforestation can be a tool for poverty	Future needs for food production are a constraint for large-scale afforestation	Afforestation can enhance human well-being by microclimatic	N/A	N/A	Afforestation using some exotic species can upset the	Afforestation may increase availability of biomass for energy use (Obersteiner	Afforestation often requires employment for active	N/A	N/A	N/A	N/A	See main text on climate mitigation and	N/A	See main text on desertification and degradation	N/A	N/A

		reduction (Holden et al 2003), afforestation can compete with land available for cropping and poor farmers often do not benefit from afforestation projects (McElwee 2009)	plans (Locatelli et al. 2015c). Global food crop demand is expected by 50%-97% between 2005 and 2050 (Valin et al. 2014). Future carbon prices will facilitate deployment of afforestation projects at expenses of food availability (adverse side-effect), but more liberalised trade in agricultural commodities could buffer food price increases following afforestation in tropical regions (Kreidenweis et al. 2016c)	ic regulation for protecting people from heat stresses (Locatelli et al. 2015c) and generally improve the cultural and recreational value of ecosystems (Knoke et al. 2014). Trends of forest resources of nations are found to positively correlate with UNDP Human Development Index (Kauppi et al. 2018)			balance of evapotranspiration regimes, with negative impacts on water availability particularly in arid regions (Ellison et al. 2017a; Locatelli et al. 2015; Trabucco et al. 2008). Afforestation in arid and semiarid regions using species that have evapotranspiration rates exceeding the regional precipitation may aggravate the groundwater decline (Locatelli et al. 2015a; Lu et al. 2016). Changes in runoff affect water supply but can also contribute to changes in flood risks, and irrigation of forest plantations can increase water consumption (Sterling et al. 2013)	et al 2006)	replanting . etc. (Mather & Murray 1987).					adaptati on				
Soil management	Increased soil organic carbon content	Can increase yields for smallholders, which can contribute to poverty	Lal (2006b) notes that "Food-grain production in developing countries can	There is evidence that increasing soil organic carbon	N/A	Gender impacts use of soil organic matter practices	Soil organic matter is known to increase water	N/A	Increased agricultural production generally	N/A	Increased agricultural production can contribute	N/A	Improved conservation agriculture	See main text on climate mitigation and	Rivers transport dissolved organic matter to oceans	See main text on desertification and degradation	N/A	N/A

		reduction, but because adoption often depends on exogenous factors these need to be taken into consideration (Wollni et al 2010; Kassie et al 2013).	be increased by 24-39 (32+-11) million Mgy-1 through improving soil quality by increasing the SOC pool and reversing degradation processes".	could be effective in reducing the prevalence of disease-causing helminths (Lal 2016; Wall et al. 2015). Also indirectly contributes to food productivity which may have impact on diets.		(Quansah et al 2001) but N/A how the relationship works in reverse.	filtration and protects water quality (Lehmann & Kleber 2015)		(Lal 2006c) contributes to increased economic growth.		to reducing inequality among smallholders (Datt & Ravallion 1998).		contributes to sustainable production goals (Hobbs et al. 2008).	adaptation	(Hedges et al 1997), but unclear if improved SOM will decrease this and by how much.			
							Various researchers showed a relationship between impact of soil erosion and degradation on water quality indicating the source of pollutant as anthropogenic and industrial activities. in China (Issaka & Ashraf 2017). Managing soil erosion improves water quality (Pimentel et al 1995)					Particulate matter pollution, a main consequence of wind erosion, imposes severe adverse impacts on materials, structures and climate which directly affect the sustainability of urban cities (Al-Thani et al. 2018)		See main text on climate mitigation and adaptation		See main text on desertification and degradation		
	Reduced soil erosion	Can increase yields for smallholders and contributes to poverty reduction (Ananda & Herath 2003)	Contributes to agricultural productivity and reduces food insecurity (Pimentel et al. 1995; Shiferaw & Holden 1999).	Contributes to food productivity and improves farmer health (Pimentel et al. 1995; Shiferaw & Holden 1999).	N/A	N/A		N/A	N/A	N/A	N/A		N/A		N/A		N/A	
	Reduced soil salinisation	Salinisation can impoverish farmers (Duraiappah 1998) therefore preventing or reversing can increase yields for smallholders and contributes to poverty reduction.	Reversing degradation contributes to food productivity and reduces food insecurity (Pimentel et al. 1995; Shiferaw & Holden 1999).	Salinisation is known to have human health impacts: wind-borne dust and respiratory health; altered ecology of mosquito-borne diseases; and mental health consequences (Jardine	N/A	N/A	Management of soil salinity improves water quality and quantity (Kotb et al. 2000; Zalidis et al 2002)						See main text on climate mitigation and adaptation		See main text on desertification and degradation			

				et al 2007)														
	Reduced soil compaction	Soil compaction and other forms of degradation can impoverish farmers (Scherr 2000); prevention of compaction thus contributes to poverty reduction.	Compactions reduces agricultural productivity and thus contributes to food insecurity (Nawaz et al 2013)	Soil compaction has human health consequences as it contributes to runoff of water and pollutants into surface and groundwater (Soane and van Ouwerkerk 1994)	N/A	N/A	Management of soil compaction improves water quality and quantity (Soane and van Ouwerkerk 1994; Zalidis et al 2002)	N/A	N/A	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
	Biochar addition to soil	Land to produce biochar may reduce land available for smallholders, and it tends to be unaffordable for poor farmers; as of yet, few biochar projects have shown poverty reduction benefits (Leach et al 2012)	Could potentially affect crop production if competition for land occurs (Ennis et al 2012)	N/A	N/A	N/A	Biochar improves soil water filtration and retention (Spokas et al 2011)	N/A	N/A	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
Other ecosystem management	Fire management	N/A	N/A	Fire management reduces health risks from particulates (Bowman & Johnston 2005).	N/A	N/A	Fires affect water quality and flow due to erosion exposure (Townsend & Douglas 2000).	N/A	N/A	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
	Reduced landslides and natural hazards	Landslides can increase vulnerability to poverty (Msilimba 2010), therefore management will reduce risks to the poor	Landslides are one of the natural disasters that have impacts on food security (de Haen & Hemrich 2007)	Managing landslides reduces health risks (Haines et al 2006)	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
	Reduced pollution	N/A	N/A	Reducing acid	N/A	N/A	Pollution increases	N/A	N/A	Management of	N/A	Management of pollution can	N/A	See main	Reduction in pollution	See main text on	N/A	N/A

	including acidification			deposition reduces health risks, including respiratory illnesses and increased morbidity (Lübker-Alcamo & Krzyzanowski 1995; Larssen et al 1999)			acidity of surface water, with likely ecological effects (Larssen et al 1999)			pollution can increase demand for new technologies (Popp 2006).		reduce exposure to health risks in urban areas (Bartone 1991)		text on climate mitigation and adaptation	can improve water quality running to oceans (Doney et al 2007).	desertification and degradation		
	Management of invasive species / encroachment	Invasive species removal policies have been beneficial to the poor (van Wilgen & Wannenburgh 2016)	IAS can compete with crops and reduce yields by billions of dollars annually (Pejchar & Mooney 2009)	IAS have strong negative effects on human well-being (Pejchar & Mooney 2009)	N/A	N/A	IAS like the golden apple snail/zebra mussel have damaged aquatic ecosystems (Pejchar & Mooney 2009)	N/A	IAS removal policies can increase employment due to need for labor (van Wilgen & Wannenburgh 2016)	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
	Restoration and avoided conversion of coastal wetlands	Impacts on poverty are mixed (Kumar et al 2011). May reduce land available for cropping, and poor design can impoverish people (Ingram et al 2006; Mangora 2011). Can also decrease vulnerability to coastal storms, however (Jones et al. 2012; Feagin et al 2010)	Mixed evidence: can affect agriculture/fisheries production when competition for land occurs, or could increase food production when ecosystems are restored (Crooks et al 2011)	Wetlands contribute to local well-being (Crooks et al 2011), and restoration generally improve the cultural and recreational value of ecosystems (Knoke et al. 2014).	N/A	N/A	Wetlands store freshwater and enhance water quality (Bobbink et al 2006)	N/A	Restoration projects often require employment for active replanting, etc. (Crooks et al. 2011).	Protecting coastal wetlands may reduce infrastructure projects in coastal areas (e.g. sea dikes, etc.) (Jones et al. 2012)	N/A	N/A	N/A	See main text on climate mitigation and adaptation	Restoration of coastal wetlands can play a large role in providing habitat for marine fish species (Bobbink et al 2006; Hale et al 2009)	See main text on desertification and degradation	N/A	N/A
	Restoration and avoided conversion of peatlands	May reduce land available for smallholders in tropical peatlands (Jewitt et al 2014)	Can affect crop production when competition for land occurs, although much use of peatlands in tropics is for palm oil, not food (Sellamuttu et al 2011)		N/A	N/A	Peatland restoration will improve water quality as they play important roles in water retention and drainage (Johnston 1991).	Peatlands in tropics are often used for biofuels and palm oil, so may reduce the availability of these (Danielsen et al 2008).	Reduced peatland exploitation may decrease GDP in Southeast Asia (Koh et al 2011)	N/A	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A

			<p>Biodiversity, and its management, is crucial for improving sustainable and diversified diets (Global Panel on Agriculture and Food Systems for Nutrition 2016). Indirectly, the loss of pollinators (due to combined causes, including the loss of habitats and flowering species) would contribute to 1.42 million additional deaths per year from non-communicable and malnutrition-related diseases, and 27.0 million lost disability-adjusted life-years (DALYs) per year (Smith et al. 2015). However, at the same time, some options to preserve biodiversity, like protected areas, may potentially conflict with food production by local communities (Molotoks et al. 2017).</p>															
	Biodiversity conservation	There is mixed evidence on the impacts of biodiversity conservation measures on poverty		Biodiversity, and its management, is crucial for improving sustainable and diversified diets (Global Panel on Agriculture and Food Systems for Nutrition 2016).	N/A	N/A	33 out of 105 of the largest urban areas worldwide rely on biodiversity conservation measures such as protected areas for some, or all, of their drinking water (Secretariat of the Convention on Biological Diversity 2008)	Some biodiversity conservation measures might increase access to biomass supplies (Erb et al. 2012)					Biodiversity conservation measures like protected areas can increase ocean biodiversity (Selig et al. 2014)	Indigenous peoples' roles in biodiversity conservation can increase institutions and conflict resolution (Garnett et al. 2018)	Indigenous peoples commonly link forest landscapes and biodiversity to tribal identities, association with place, kinship ties, customs and protocols, stories, and songs (Gould 2014; Lyver et al. 2017a, b).			
	Enhanced weathering of minerals	N/A	N/A	N/A	N/A	N/A	Mineral weathering can affect the chemical composition of soil and surface waters (Katz	N/A	N/A	Will require development of new technologies (Schuiling and Krijgsman	N/A	N/A	N/A	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A

							1989)			2006)								
CDR	Bioenergy and BECCS	Bioenergy production could create jobs in agriculture, but could also compete for land with alternative uses. Therefore, bioenergy could have positive or negative effects on poverty rates among smallholders, among other social effects (IPCC 2018).	Biofuel plantations may lead to decreased food security through competition for land (Locatelli et al. 2015c). BECCS will likely lead to significant trade-offs with food production (Popp et al. 2011c; Smith et al. 2016b).	BECCS could have positive effects through improvements in air and water quality (IPCC 2018), but BECCS could have negative effects on health and wellbeing through impacts on food systems (Burns and Nicholson 2017). Additionally, there is a non-negligible risk of leakage of CO2 (IPCC 2018).	No direct interaction (IPCC 2018).	No direct interaction (IPCC 2018).	Will likely require water for plantations of fast growing trees and models show high risk of water scarcity if BECCS is deployed on widespread scale (IPCC 2018).	BECCS and biofuels can contribute up to 300 EJ of primary energy by 2100 (cross-chapter box 7 on bioenergy); bioenergy can provide clean, affordable energy (IPCC 2018).	Access to clean, affordable energy will help economic growth (IPCC 2018).	BECCS will require development of new technologies (Smith et al. 2016c).	No direct interaction (IPCC 2018).	No direct interaction (IPCC 2018).	Switching to bioenergy reduces depletion of natural resources (IPCC 2018).	See main text on climate mitigation and adaptation.	Reductions in carbon emissions will reduce ocean acidification. See main text on climate mitigation.	See main text on desertification and degradation.	No direct interaction (IPCC 2018).	No direct interaction (IPCC 2018).

Table SM6.13 Impacts on the UN SDG of integrated response options based on value chain interventions

Integrated response options based on value chain management	GOAL 1: No Poverty	GOAL 2: Zero Hunger	GOAL 3: Good Health and Well-being	GOAL 4: Quality Education	GOAL 5: Gender Equality	GOAL 6: Clean Water and Sanitation	GOAL 7: Affordable and Clean Energy	GOAL 8: Decent Work and Economic Growth	GOAL 9: Industry, Innovation and Infrastructure	GOAL 10: Reduced Inequality	GOAL 11: Sustainable Cities and Communities	GOAL 12: Responsible Consumption and Production	GOAL 13: Climate Action	GOAL 14: Life Below Water	GOAL 15: Life on Land	GOAL 16: Peace and Justice Strong Institutions	GOAL 17: Partnerships to achieve the Goal
Demand management Dietary change	Reduced meat consumption can free up land for other activities to reduce poverty (Röös et al. 2017; Stoll-Kleemann and O’Riordan 2015). However, reduced demand for livestock will have negative effect on pastoralists and could suppress	High-meat diets in developed countries may limit improvement in food security in developing countries (Rosegrant et al. 1999); dietary change can contribute to	Overnutrition contributes to worse health outcomes, including diabetes and obesity (Tilman and Clark 2014a; McMichael et al. 2007). Dietary change away from meat consumption	No direct interaction (IPCC 2018)	No direct interaction (IPCC 2018)	Reduced meat consumption will reduce water consumption. (Muller et al. 2017b) found that lower impact agriculture could be practiced if dietary change and	Dietary shifts away from meat to fish/fruits/vegetables increases energy use in the US by over 30% (Tom et al. 2016)	Health costs of meat-heavy diets add to health care costs and reduce GDP (Popkin 2008)	N/A	There are currently large discrepancies in diets between developed and developing nations (Sans & Combris 2015). Dietary change will reduce food inequality by reducing meat overconsumption in Western countries and	Dietary change is most needed in urbanised, industrialised countries and can help contribute to demand for locally grown fruits and vegetables (Tom et al. 2016)	A dietary shift away from meat can contribute to sustainable consumption by reducing greenhouse gas emissions and reducing cropland and pasture requirements (Stehfest et al. 2009; Bajželj	See main text on climate mitigation and adaptation	Dietary change away from meat might put increased pressure on fish stocks (Vranken et al. 2014; Mathijs 2015). Overall reduced emissions	See main text on desertification and degradation	N/A	N/A

		demand for other inputs (grains) that would affect poor farmers (Garnett 2011; IPCC SR15)	food security goals (Godfray et al. 2010a; Bajželj et al. 2014)	has major health benefits, including reduced heart disease and mortality (Popkin 2008; Friel et al. 2008). Dietary change could contribute to 5.1 million avoided deaths per year (Springmann et al. 2016)			waste reduction were implemented, leading to lower GHG emissions, lower rates of deforestation, and decreases in use of fertiliser (nitrogen and phosphorus), pesticides, water and energy. However, Tom et al. (2016) found water footprints of fruit/veg dietary shift in the US to increase by 16%				free up some cereals for consumption in poorer diets (Rosegrant et al. 1999)		et al. 2014).		would decrease rate of ocean acidification (Doney et al. 2009)			
	Reduced post-harvest losses	Reducing food losses from storage and distribution operation can increase economic well-being without additional investment in production activities (Bradford et al. 2018; Temba et al. 2016)	Reducing food losses increases food availability, nutrition, and lower prices (Sheahan and Barrett 2017b; Abass et al. 2014; Affognon et al. 2015)	Improved storage enhances food quality and can reduce mycotoxin intake (Bradford et al. 2018; Temba et al. 2016; Stathers et al. 2013; Tirado et al. 2010) especially in humid climates (Bradford et al. 2018). The perishability and safety of fresh foods are highly susceptible to temperature increase (Bisbis et al. 2018; Ingram et al. 2016a).	Reduced losses can increase income that could be spent on education, but no data available	Postharvest losses do have a gender dimension (Kaminski and Christiaensen 2014), but unclear if reducing losses will contribute to gender equality (Rugumamu 2009)	Kummu et al. (2012a) reported that 24% of global freshwater use and 23% of global fertiliser use is attributed to food losses. Reduced post harvest losses can decrease need for additional agricultural production and irrigation.	Reduced losses would reduce energy demands in production; 2030 +- 160 trillion BTU of energy were embedded in wasted food in 2007 in the US (Cuéllar and Webber 2010)	In East and Southern Africa, postharvest loss for six major cereals was USD1.6 billion or 15% of total production value; reducing losses would thus boost GDP substantially in developing countries with PHL (Hodges et al. 2011)	Reducing PHL can involve improving infrastructure for farmers and marketers (Parfitt et al. 2010)	Poorer households tend to experience more PHL, and thus reducing PHL can contribute to reducing inequality among farmers (Hodges et al. 2011).	N/A	Reducing PHL contributes to sustainable production goals (Parfitt et al. 2010)	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	Post harvest losses contribute to higher food prices and constraints on trade (Tefera 2012)
	Reduced food waste (consumer or retailer)	Food waste tends to rise as incomes rise (Parfitt et al. 2010; Liu et al. 2013), so it is not clear what the relationship to poverty is. Could be potentially beneficial as it would free up	People who are already food insecure tend not to waste food (Nahman et al. 2012). Reduced food waste would	Food waste can increase with healthier diets (Parizeau et al. 2015). Health and safety standards can restrict some approaches to reducing food	N/A	Reducing food waste within households often falls to women (Stefan et al. 2013) and can increase their labor workload	Kummu et al. (2012a) reported that 24% of global freshwater and 23% of global fertiliser is used in the production of	Reduced losses would reduce energy demands in production; 2030 +- 160 trillion BTU of energy were embedded in wasted food in 2007 in the US (Cuéllar and Webber 2010). Food waste can be a	Waste generation has grown faster than GDP in recent years (Thogerson 1996). Households in the UK throw out USD745	Food waste could be an important source of needed chemicals for industrial development in resource constrained countries (Lin et	Wealthier households tend to waste more food (Parfitt et al. 2010), but unclear how reducing waste may contribute to reducing inequality.	There have been large increases in the throughput of materials such as the food-waste stream, import and solid-waste	Post-consumer food waste in industrialised countries (222 million ton) is almost as high as the total net food production in sub-Saharan Africa (230	See main text on climate mitigation and adaptation	Reducing food waste may be related to food packaging, which is a major source of ocean pollution,	See main text on desertification and degradation	N/A	Food waste can contribute to higher food prices and constraints on trade (Tefera 2012)

		money to spend on other activities (Dorward 2012). Redistribution of food surplus to the poor could also have impacts on poverty (Papargyropoulou et al. 2014)	increase the supply of food (FAO 2011; Smith 2013), but it is unclear if this would benefit those who are food insecure in developing countries (Hertel and Baldos 2016).	waste (Halloran et al. 2014). Changes in packaging to reduce waste might have negative health impacts (e.g. increased contamination) (Claudio 2012)		(Hebrok and Boks 2017). Women also generate more food waste and could be a site for intervention (Thyberg and Tonjes 2016)	food losses, so reduction in food waste could provide significant co-benefits for freshwater provision and on nutrient cycling (Kummu et al. 2012). Muller et al. (2017b) found that lower impact agriculture could be practiced if dietary change and waste reduction were implemented, leading to lower GHG emissions, lower rates of deforestation, and decreases in use of fertiliser (nitrogen and phosphorus), pesticides, water and energy.	sustainable source of biofuel (Uçkun Kiran et al. 2014)	of food and drink each year as food waste; South Africans throw out USD 7billion worth of food per year (Nahman and de Lange 2013). Reductions of postconsumer waste would increase household income (Hodges et al. 2011)	al. 2013)		accumulation in urban areas (Grimm et al. 2008). Reducing compostable food waste reduces need for landfills (Smit and Nasr 1992; Zaman and Lehmann 2011)	million ton). (FAO 2011), thereby reducing waste contributes to sustainable consumption.		but relationship is not known (Hornweg et al 2013)			
	Material substitution	N/A	Could increase demand for wood and compete with land for agriculture, but no evidence of this yet.	N/A	N/A	N/A	If water is used efficiently in production of wood, likely to be positive impact over cement production (Gustavsson and Sathre 2011)	Concrete frames require 60-80% more energy than wood (Börjesson and Gustavsson 2000). Material substitution can reduce embodied energy of buildings construction by up to 20% (Thormark 2006; Upton et al. 2008)	The relationship between material substitution and GDP growth is unclear (Moore et al. 1996)	Material substitution may reduce need for industrial production of cement etc. (Petersen and Solberg 2005)	N/A	Changing materials for urban construction can reduce cities' ecological footprint (Zaman and Lehmann 2013)	Material substitution is a form of sustainable production/consumption which replaces cement and other energy-intensive materials with wood (Fiksel 2006)	See main text on climate mitigation and adaptation	Overall reduced emissions rate of ocean acidification (Doney et al. 2009)	See main text on desertification and degradation	N/A	N/A
Supply management	Sustainable sourcing	Value adding has been promoted as a successful poverty reduction strategy in many countries (Lundy et al. 2002; Whitfield 2012; Swanson 2006). Volatility of food supply and food price spikes in 2007 increased the number of people	Poor farmers can benefit from value-adding and new markets (Bamman 2007) and may help to improve food security by increasing its economic performance	Value-chains can help increase the nutritional status of food reaching consumers (Fan et al. 2012)	Value-adding can increase income that could be spent on education, but no data available	Women are highly employed in value-added agriculture in many developing countries, but do not always gain substantive benefits (Dolan and Sorby 2003).	Value-added products might require additional water use (Guan and Hubacek 2007), but depends on context.	N/A	Value-adding and export diversification generates additional employment and expands GDP in developing countries in particular (Newfarmer et al. 2009)	Value adding can create incentives to improve infrastructure in processing (Delgado 2010). Expanding value chains can incorporate new sources of food producers into industrial systems of	Value-adding can be an important component of employment for poorer areas, and can contribute to reductions in overall inequality. However, data shows high-value agriculture	Value-adding can increase incentives to keep peri-urban agriculture, but faces threats from rising land prices in urban areas (Midmore and Jansen	Value-adding in agriculture (e.g. fair trade, organic) can be an important source of sustainable consumption and production (de Haen and Réquillart 2014)	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	Value-adding has a strong relationship to expanding trade in developing countries in particular (Newfarmer et al. 2009)

		under the poverty line by between 100 million people (Ivanic and Martin 2008) to 450 million people (Brinkman et al. 2009), and caused welfare losses of 3% or more for poor households in many countries (Zezza et al. 2009).	and revenues for local farmers (Reidsma et al. 2010). However, much value-adding is captured upstream, not by poor producers (McMichael and Schneider 2011b). Food prices strongly affect food security (Lewis and Wiham 2012; Regmi and Meade 2013; Fujimori et al. 2018a), and policies to decrease volatility will likely have strong impacts on food security (Timmer 2009; Torlesse et al. 2003b; Raleigh et al. 2015b).			Value-chains that target women could increase gender equity, but data is scarce (Gengenbach et al. 2018)			distribution (Bloom and Hinrichs 2011)	is not always a pathway toward enhanced welfare (Dolan and Sorby 2003), and much value-adding is captured not by smallholders but higher up the chain (Neilson 2007)	2003)						
Management of supply chains	Reducing food transport costs generally helps poor farmers (Altman et al. 2009). More than USD200 million is generated in fresh fruit and veg trade between Kenya and the UK; much has contributed to poverty reduction and better transport could increase the amount generated (MacGregor and Vorley 2006; Muriithi and Matz 2015). Volatility of food supply and food price spikes in 2007 increased the number of people under the poverty line by between 100 million people (Ivanic and Martin	Improving efficiency can reduce food waste and health risks associated with poor storage management practices (James and Bradford et al. 2018; Temba et al. 2016; Stathers et al. 2013; Tirado et al. 2010). There is some limited evidence that improved transport on-farm increases	Access to quality food is a major contributor to whether a diet is healthy or not (Neff et al. 2009). Increased distribution and access of packaged foods however can decrease health outcomes (Galal et al. 2010; Monteiro et al. 2011)	Reduction in staple food price costs to consumers in Bangladesh from food stability policies saved rural households USD887 million total (Torlesse et al. 2003b), but N/A if this increased spending on education in households	Women and girls are often the most effected ones in households when there are food shortages (Kerr 2005; Hadley et al. 2008)	Food imports can contribute to water scarcity through "embodied" or "virtual" water accounting (Yang and Zehnder 2002; Guan and Hubacek 2007; Hanjra and Qureshi 2010; Jiang 2009)	Food supply chains and flows have adverse effects due to reliance on non-renewable energy (Kurian 2017; Scott 2017). Shifts to biofuels can destabilise food supplies (Tirado et al. 2010; Chakauya et al. 2009)	Food supply instability is often driven by price volatility, which can be driven by rapid economic growth and which can contribute to consumer price inflation and higher import costs as a percentage of GDP leading to account deficits (Gilbert and Morgan 2010)	Excessive disruptions in food supply can place strains on infrastructure (e.g. needing additional storage facilities) (Yang and Zehnder 2002). Improved food transport can create demands for improved infrastructure (Akkerman et al. 2010; Shively and Thapa 2016). For example, weatherproofing transport systems and improving the efficiency of food trade (Ingram et al. 2016a; Stathers et al. 2013)	Food volatility makes it more challenging to supply food to vulnerable regions, and likely increases inequality (Baldos and Hertel 2015; Frank et al. 2017; Porter et al. 2014; Wheeler and von Braun 2013). Improved food distribution could reduce inequality in access to high quality nutritious foods. Food insecure consumers benefit from better access and distribution (e.g. food deserts) (Ingram 2011;	Improved food distribution can contribute to better food access and stronger urban communities (Kantor 2001; Hendrickson et al. 2006). Food price spikes often hit urban consumers the hardest in food importing countries, and increasing stability can reduce risk of food riots (Cohen and Garrett 2010)	Improved storage and distribution are likely to contribute to sustainable production by impacting biomass of paper/card and aluminum and iron-ore mining used for food packaging (Ingram et al. 2016a).	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	Better transport improves chances for expanding trade in developing countries (Newfarmer et al. 2009). Well-planned trade systems may act as a buffer to supply food to vulnerable regions (Baldos and Hertel 2015; Frank et al. 2017; Porter et al. 2014; Wheeler and von Braun 2013).

		2008) to 450 million people (Brinkman et al. 2009), and caused welfare losses of 3% or more for poor households	food security in developing countries (Hine 1993).							especially in countries with inadequate infrastructure and weak food distribution systems (Vermeulen et al. 2012a), can strengthen climate resilience against future climate-related shocks (Ingram et al. 2016a; Stathers et al. 2013).	Coveney and O'Dwyer 2009)							
		Regional food systems present opportunities for interconnectedness of the food system 's component resilient food supply systems and city-regions have an important role (Brinkley et al. 2016; Rocha 2016). However, mixed evidence on if urban agriculture contributes to poverty reduction (Ellis and Sumberg 1998)	Food insecurity in urban areas is often invisible (Crush and Frayne 2011). Improved urban food systems manage flows of food into, within, and out of the cities and have large role to play in reducing urban food security (Smit 2016; Benis and Ferrão 2017a; Brinkley et al. 2016; Rocha 2016; Maxwell and Wiebe 1999), particularly in fostering regional food self-reliance (Aldababseh et al. 2018; Bustamante et al. 2014b).	Since urban poor spend a great deal of their budget on food and urban diets are exposed to more unhealthy 'fast foods' (Dixon et al. 2007), local urban food systems can contribute to enhanced nutrition in urban areas (Tao et al. 2015; Maxwell 1999; Neff et al. 2009). However, local urban agriculture also may introduce pollution into food system through toxins in soil and water (Binns et al. 2003)	School feeding programs in urban areas can increase educational attendance and outcomes (Ashe and Sonnino 2013)	Urban and Peri-urban Agriculture and Forestry (UPAF) addresses gender-based differences in accessing food since women play an important role in the provisioning of urban food (Tao et al. 2015; Binns and Lynch 1998). Women also dominate informal urban food provisioning (wet markets, street food) (Smith 1998)	Water access often a constraint on urban agriculture (de Bon et al. 2010; Badami and Ramankutty 2015). Urban agriculture can exacerbate urban water pollution problems (pesticide runoff, etc) (Pothukuchi and Kaufman 1999)	Local food production and use can reduce energy use, due to lower demand of resources for production, transport and infrastructure (Lee-Smith 2010), but depends on context (Mariola 2008; Coley et al. 2009)	Urban food systems have as one aim to stimulate local economic development and increase employment in urban agriculture and food processing (Smith 1998). As many as 50% of some cities' retail jobs are in food-related sector (Pothukuchi and Kaufman 1999)	Urban food provisioning creates demands for expanded infrastructure in processing, refrigeration, and transportation (Pothukuchi and Kaufman 1999)	Many UFS in global South (e.g. Horizonte, Belo Horizonte, Brazil) have goals to reduce inequality in access to food. (Dixon et al. 2007; Allen 2010)	UFS aim at improving the health status of urban dwellers, reducing their exposure to pollution levels, and stimulating economic development (Tao et al. 2015)	UFS aim to combine sustainable production and consumption with local foodsheds (Tao et al. 2015; Allen 2010)	See main text on climate mitigation and adaptation	Overall reduced emissions would decrease rate of ocean acidification (Doney et al. 2009)	See main text on desertification and degradation	Building a resilient regional food system requires adjusting to the social and cultural environment and locally-specific natural resource base and building local institutions (Akhtar et al. 2016). Production of food within cities can potentially lead to less likelihood of urban food shortages and conflicts (Cohen & Garrett 2010).	N/A
		Improved food processing and retailing	Efficiency in food processing and supply chains can contribute to more food reaching consumers and	Improved processing and distribution & storage systems can provide safer and healthier food to consumers (Vermeulen et	N/A	Improved food processing can displace street vendors and informal food sellers, who are predominantly women	Food processing and packaging activities such as washing, heating, cooling are heavily	Food processing activities such as heating and cooling are heavily dependent on energy so improved efficiency could reduce energy demand (Garcia and	Phytosanitary barriers currently prevent much food export from developing countries, and improvements in processing	Improvements in processing, refrigeration, and transportation will require investments in improved infrastructure	N/A	Improved food transport can reduce cities' ecological footprints and reduce overall emissions (Du et al.	Improved food processing and agro-retailing contributes to sustainable production (Ingram 2011)	See main text on climate mitigation and adaptation	Overall reduced emissions would decrease rate of ocean acidification (Doney et	See main text on desertification and degradation	N/A	Improved processing increases chances for expanding trade in developing countries (Newfarmer

			improved nutrition (Vermeulen et al. 2012a; Keding et al. 2013)	al. 2012a) and reduce food waste and health risks associated with poor storage management practices (James and James 2010a), although overpackaged prepared foods that are less healthy are also on rise (Monteiro 2009; Monteiro et al. 2011).		(Smith 1998; Dixon et al. 2007)	dependent on freshwater so improved postharvest storage and distribution could reduce water demand via more efficiently performing systems (Garcia and You 2016).	You 2016).	would increase exports and GDP (Henson and Loader 2001; Jongwanich 2009).	(Ingram 2011)		2006)		al. 2009)		et al. 2009)		
Improved energy use in food systems	Might possibly have impact on poverty by reducing farmer costs, but no data.		Utilising energy-saving strategies can support reduced food waste (Ingram et al. 2016a) and increased production efficiencies (Smith and Gregory 2013).	Organic agriculture is associated with increased energy efficiency, which have can have co-benefits by reduced exposure to agrochemicals by farm workers (Gomiero et al. 2008)	N/A	Increased efficiency might reduce women's labor workloads on farms (Rahman 2010) but data is scarce.	Increased energy efficiency (e.g. in irrigation) can lead to more efficient water use (Rothausen and Conway 2011; Ringler and Lawford 2013)	Increased energy efficiency will reduce demands for energy but can have rebound effect in expanded acreage (Swanton et al. 1996)	There is no clear association between higher energy use in agriculture and economic growth; these have become decoupled in many countries (Bonny 1993). Data is unclear though on economic impacts of potential cost savings.	N/A	N/A	N/A	Reducing energy use in agriculture contributes to sustainable production goals (Ingram et al. 2016a).	See main text on climate mitigation and adaptation	Overall reduced emissions would decrease rate of ocean acidification (Doney et al. 2009).	See main text on desertification and degradation	N/A	N/A

Table SM6.14 Impacts on the UN SDG of integrated response options based on risk management

<u>Integrated response options based on risk management</u>	GOAL 1: No Poverty	GOAL 2: Zero Hunger	GOAL 3: Good Health and Well-being	GOAL 4: Quality Education	GOAL 5: Gender Equality	GOAL 6: Clean Water and Sanitation	GOAL 7: Affordable and Clean Energy	GOAL 8: Decent Work and Economic Growth	GOAL 9: Industry, Innovation and Infrastructure	GOAL 10: Reduced Inequality	GOAL 11: Sustainable Cities and Communities	GOAL 12: Responsible Consumption and Production	GOAL 13: Climate Action	GOAL 14: Life Below Water	GOAL 15: Life on Land	GOAL 16: Peace and Justice Strong Institutions	GOAL 17: Partnerships to achieve the Goal
Management of urban sprawl	Inner city poverty closely associated with urban sprawl in US context (Frumkin 2002; Powell 1999; Jargowsky	There are likely to be some benefits for food security since it is often agricultural land that is	Strong association between urban sprawl and poorer health outcomes	N/A	N/A	Urban sprawl is associated with higher levels of water pollution due to loss of filtering vegetation and increasing impervious	Sprawling or informal settlements often do not have access to electricity or other services, increasing	Sprawl is associated with rapid economic growth in some areas (Brueckner 2000).	Urban sprawl often increases public infrastructure costs (Brueckner 2000), and densification and	Urban sprawl is associated with inequality (Jargowsky 2002)	Urban sprawl is associated with unsustainability, including increased transport and CO ₂ emissions, lack of access to services,	Reducing urban sprawl and promoting community gardens and periurban agriculture can contribute to	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	There are debates over the role of urban sprawl in reducing social capital and weakening	N/A

		2002; Deng and Huang 2004)	sealed by the urban expansion (Barbero-Sierra et al. 2013a). Some evidence for sprawl reducing food production, particularly in China (Chen 2007b)	(air pollution, obesity, traffic accidents) (Frumkin 2002; Lopez 2004; Freudenberg et al. 2005)			surfaces (Romero and Ordenes 2004; Tu et al. 2007)	chances HH rely on dirty fuels (Dhingra et al. 2008)	Reducing urban sprawl is part of many managed "smart growth" plans, which may reduce overall economic growth in return for sustainability benefits (Godschalk 2003)	redevelopment can improve equality of access to infrastructure (Jenks and Burgess 2000).		and loss of civic life (Kombe 2005; Andersson 2006). Sustainable cities include compactness, sustainable transport, density, mixed land uses, diversity, passive solar design, and greening (Chen et al. 2008; Jabareen 2006; Andersson 2006)				participatory governance in cities (Frumkin 2002; Nguyen 2010)		
		Diversification is associated with increased welfare and incomes and decreased levels of poverty in several country studies (Arslan et al. 2018b; Asfaw et al. 2018).	Diversification is associated with increased access to income and additional food sources for the household (Pretty 2003); likely some food security benefits but diversification can also lead to more purchased (unhealthy) foods (Niehof 2004; Barrett et al. 2001)	More diversified livelihoods have diversified diets which have better health outcomes (Block and Webb 2001; Kadiyala et al. 2014) particularly for women and children (Pretty 2003)	More diversified households tend to be more affluent, & have more income for education (Ellis 1998; Estudillo and Otsuka 1999; Steward 2007), but diversification through migration may reduce educational outcomes for children (Gioli et al. 2014)	Women are participants in and benefit from livelihood diversification, such as having increased control over sources of HH income (Smith 2015), although it can increase their labor requirements (Angeles and Hill 2009)	Lack of access to affordable water may inhibit livelihood diversification (Calow et al. 2010)	Access to clean energy can provide additional opportunities for livelihood diversification (Brew-Hammond 2010; Suckall et al. 2015)	Livelihood diversification by providing additional work opportunities (Ellis 1998; Niehof 2004)	N/A	The relationship between livelihood diversification and inequality is inconclusive (Ellis 1998). In some cases diversification on reduced inequality (Adams 1994) while it increases it (Reardon et al 2000)	One part of urban livelihoods in developing countries are linkages between rural and urban areas through migration and remittances (Rakodi 1999; Rakodi & Lloyd 2002); this livelihood diversification can strengthen urban income (Ricci 2012)	Livelihood diversification does not always lead to sustainable production and consumption choices, but it can strengthen autonomy potentially leading to better choices (Elmqvist and Olsson 2007; Schneider and Niederle 2010)	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	N/A	N/A
		Many hundreds of millions of smallholders still rely on local seeds; without them they would have to find money to buy commercial seeds (Altieri et al. 2012b; McGuire and Sperling 2016; Howard 2015)	Local seeds revive and strengthen local food systems (McMichael and Schneider 2011b) and lead to more diverse and healthy food in areas with strong food sovereignty networks (Coomes et al. 2015a; Bisht et al. 2018). However local seeds often are less productive than improved varieties.	Local seed use is associated with fewer pesticides (Altieri et al. 2012b); loss of local seeds and substitution by commercial seeds is perceived by farmers to increase health risks (Mazzeo and Brenton 2013), although overall literature on links between food sovereignty and health is weak (Jones	N/A	Women play important roles in preserving and using local seeds (Ngoyea and Kumarakulasingam 2017; Bezner Kerr 2013) and sovereignty movements paying more attention to gender needs (Park et al. 2015)	Local seeds often have lower water demands, as well as less use of pesticides that can contaminate water (Adhikari 2014)	N/A	Food sovereignty supporters believe protecting smallholder agriculture provides more than commercial agriculture (Kloppenber 2010)	N/A	Seed sovereignty advocates believe it will contribute to reduced inequality (Wittman 2011; Park et al. 2015) but there is inconclusive empirical evidence.	Seed sovereignty can help sustainable urban gardening (Demaily and Darly 2017) which can be part of a sustainable city by providing fresh, local food (Leitgeb et al. 2016).	Locally developed seeds can both help protect local agrobiodiversity and can often be more climate resilient than generic commercial varieties, leading to more sustainable production (Coomes et al. 2015a; van Niekerk and Wynberg 2017a).	See main text on climate mitigation and adaptation	N/A	See main text on desertification and degradation	Seed sovereignty is positively associated with strong local food movements, which contribute to social capital (McMichael and Schneider 2011b; Coomes et al. 2015a; Grey and Patel 2015).	Seed sovereignty could be seen as threat to free trade and imports of genetically modified seeds (Kloppenber 2010; Howard 2015; Kloppenburg 2014)

17		

1 **Executive summary**

2 **Increases in global mean surface temperature are projected to result in continued permafrost**
3 **degradation and coastal degradation (*high confidence*), increased wildfire, decreased crop yields**
4 **in low latitudes, decreased food stability, decreased water availability, vegetation loss (*medium***
5 ***confidence*), decreased access to food and increased soil erosion (*low confidence*). There is *high***
6 ***agreement and high evidence* that increases in global mean temperature will result in continued**
7 **increase in global vegetation loss, coastal degradation, as well as decreased crop yields in low**
8 **latitudes, decreased food stability, decreased access to food and nutrition, and *medium***
9 ***confidence* in continued permafrost degradation and water scarcity in drylands. Impacts are**
10 **already observed across all components (*high confidence*). Some processes may experience**
11 **irreversible impacts at lower levels of warming than others. There are high risks from permafrost**
12 **degradation, and wildfire, coastal degradation, stability of food systems at 1.5°C while high risks from**
13 **soil erosion, vegetation loss and changes in nutrition only occur at higher temperature thresholds due**
14 **to increased possibility for adaptation (*medium confidence*). {7.2.2.1, 7.2.2.2, 7.2.2.3; 7.2.2.4; 7.2.2.5;**
15 **7.2.2.6; 7.2.2.7; Figure 7.1}**

16
17 **These changes result in compound risks to food systems, human and ecosystem health,**
18 **livelihoods, the viability of infrastructure, and the value of land (*high confidence*). The**
19 **experience and dynamics of risk change over time as a result of both human and natural processes**
20 **(*high confidence*). There is *high confidence* that climate and land changes pose increased risks at**
21 **certain periods of life (i.e. to the very young and ageing populations) as well as sustained risk to those**
22 **living in poverty. Response options may also increase risks. For example, domestic efforts to insulate**
23 **populations from food price spikes associated with climatic stressors in the mid-2000s inadequately**
24 **prevented food insecurity and poverty, and worsened poverty globally. {7.2.1, 7.2.2, 7.3, Table 7.1}**

25
26 **There is significant regional heterogeneity in risks: tropical regions, including Sub-Saharan**
27 **Africa, Southeast Asia and Central and South America are particularly vulnerable to decreases**
28 **in crop yield (*high confidence*). Yield of crops in higher latitudes may initially benefit from warming**
29 **as well as from higher CO₂ concentrations. But temperate zones, including the Mediterranean, North**
30 **Africa, the Gobi desert, Korea and western United States are susceptible to disruptions from increased**
31 **drought frequency and intensity, dust storms and fires (*high confidence*). {7.2.2}**

32
33 **Risks related to land degradation, desertification and food security increase with temperature**
34 **and can reverse development gains in some socio-economic development pathways (*high***
35 ***confidence*) . SSP1 reduces the vulnerability and exposure of human and natural systems and**
36 **thus limits risks resulting from desertification, land degradation and food insecurity compared**
37 **to SSP3 (*high confidence*). SSP1 is characterized by low population growth, reduced inequalities,**
38 **land use regulation, low meat consumption, increased trade and few barriers to adaptation or**
39 **mitigation. SSP3 has the opposite characteristics. Under SSP1, only a small fraction of the dryland**
40 **population (around 3% at 3°C for the year 2050) will be exposed and vulnerable to water stress.**
41 **However under SSP3, around 20% of dryland populations (for the year 2050) will be exposed and**
42 **vulnerable to water stress by 1.5°C and 24% by 3°C. Similarly under SSP1, at 1.5°C, 2 million people**
43 **are expected to be exposed and vulnerable to crop yield change. Over 20 million are exposed and**
44 **vulnerable to crop yield change in SSP3, increasing to 854 million people at 3°C (*low confidence*).**
45 **Livelihoods deteriorate as a result of these impacts, livelihood migration is accelerated, and strife and**
46 **conflict is worsened (*medium confidence*). {Cross-Chapter Box 9 in Chapter 6, 7.2.2, 7.3.2, Table 7.1,**
47 **Figure 7.2}**

48

1 **Land-based adaptation and mitigation responses pose risks associated with the effectiveness and**
2 **potential adverse side-effects of measures chosen (*high confidence*).** Adverse side-effects on food
3 security, ecosystem services and water security increase with the scale of bioenergy and bioenergy
4 with carbon capture and storage (BECCS) deployment. In a SSP1 future, bioenergy and BECCS
5 deployment up to 6 Mkm² is compatible with sustainability constraints, whereas risks are already high
6 in a SSP3 future for this scale of deployment. {7.2.3}

7
8 **There is *high confidence* that policies addressing vicious cycles of poverty, land degradation and**
9 **greenhouse gas emissions implemented in a holistic manner can achieve climate resilient**
10 **sustainable development. Choice and implementation of policy instruments determine future**
11 **climate and land pathways (*medium confidence*).** Sustainable development pathways (described in
12 SSP1) supported by effective regulation of land use to reduce environmental trade-offs, reduced
13 reliance on traditional biomass, low growth in consumption and limited meat diets, moderate
14 international trade with connected regional markets, and effective GHG mitigation instruments) can
15 result in lower food prices, fewer people affected by floods and other climatic disruptions, and
16 increases in forested land (*high agreement, limited evidence*) (SSP1). A policy pathway with limited
17 regulation of land use, low technology development, resource intensive consumption, constrained
18 trade, and ineffective GHG mitigation instruments can result in food price increases, and significant
19 loss of forest (*high agreement, limited evidence*) (SSP3). {3.7.5, 7.2.2, 7.3.4, 7.5.5, 7.5.6, Table 7.1,
20 Cross-Chapter Box 12: Traditional Biomass, in this chapter}

21
22 **Delaying deep mitigation in other sectors and shifting the burden to the land sector, increases**
23 **the risk associated with adverse effects on food security and ecosystem services(*high confidence*).**
24 The consequences are an increased pressure on land with higher risk of mitigation failure and of
25 temperature overshoot and a transfer of the burden of mitigation and unabated climate change to
26 future generations. Prioritising early decarbonisation with minimal reliance on carbon dioxide
27 removal (CDR) decreases the risk of mitigation failure (*high confidence*). {2.5, 6.2, 6.4, 7.2.1, 7.2.2,,
28 7.2.3, 7.5.6, 7.5.7, Cross-Chapter Box 9 in Chapter 6, 7.5.6}

29
30 **Trade-offs can occur between using land for climate mitigation or sustainable development goal**
31 **(SDG) 7 (affordable clean energy) with biodiversity, food, ground-water and riverine ecosystem**
32 **services (*medium confidence*).** There is *medium confidence* that trade-offs currently do not figure
33 into climate policies and decision making. Small hydro power installations (especially in clusters) can
34 impact downstream river ecological connectivity for fish (*high agreement, medium evidence*). Large
35 scale solar farms and wind turbine installations can impact endangered species and disrupt habitat
36 connectivity (*medium agreement, medium evidence*). Conversion of rivers for transportation can
37 disrupt fisheries and endangered species (through dredging and traffic) (*medium agreement, low*
38 *evidence*). {7.5.6}

39
40 **The full mitigation potential assessed in this report will only be realised if agricultural emissions**
41 **are included in mainstream climate policy (*high agreement, high evidence*) .** Carbon markets are
42 theoretically more cost-effective than taxation but challenging to implement in the land-sector (*high*
43 *confidence*) Carbon pricing (through carbon markets or carbon taxes) has the potential to be an
44 effective mechanism to reduce GHG emissions, although it remains relatively untested in agriculture
45 and food systems. Equity considerations can be balanced by a mix of both market and non-market
46 mechanisms (*medium evidence, medium agreement*). Emissions leakage could be reduced by multi-
47 lateral action (*high agreement, medium evidence*). {7.4.6, 7.5.5, 7.5.6, Cross Chapter Box 9 in
48 Chapter 6}

1 **A suite of coherent climate and land policies advances the goal of the Paris Agreement and the**
2 **land-related SDG targets on poverty, hunger, health, sustainable cities and communities,**
3 **responsible consumption and production, and life on land. There is *high confidence* that acting**
4 **early will avert or minimise risks, reduce losses and generate returns on investment** . The
5 economic costs of action on sustainable land management, mitigation, and adaptation are less than the
6 consequences of inaction for humans and ecosystems (*medium confidence*). Policy portfolios that
7 make ecological restoration more attractive, people more resilient - expanding financial inclusion,
8 flexible carbon credits, disaster risk and health insurance, social protection and adaptive safety nets,
9 contingent finance and reserve funds, and universal access to early warning systems – could save
10 USD 100 billion a year, if implemented globally. {7.3.1, 7.4.7, 7.4.8, 7.5.6, Cross-chapter box 10:
11 Economic Dimensions, in this chapter}

12
13 **Coordination of policy instruments across scales, levels, and sectors advances co-benefits,**
14 **manages land and climate risks, advances food security, and addresses equity concerns (*medium***
15 ***confidence*).** Flood resilience policies are mutually reinforcing and include flood zone mapping,
16 financial incentives to move, and building restrictions, and insurance. Sustainability certification,
17 technology transfer, land use standards and secure land tenure schemes, integrated with early action
18 and preparedness, advance response options. Sustainable land management improves with investment
19 in agricultural research, environmental farm practices, agri-environmental payments, financial support
20 for sustainable agricultural water infrastructure (including dugouts), agriculture emission trading, and
21 elimination of agricultural subsidies (*medium confidence*). Drought resilience policies (including
22 drought preparedness planning, early warning and monitoring, improving water use efficiency),
23 synergistically improve agricultural producer livelihoods and foster sustainable land management.
24 {3.7.5, Cross-Chapter Box 5 in Chapter 3, 7.4.3, 7.4.6, 7.5.6, 7.4.8, , 7.5.6, 7.6.3}

25
26 **Technology transfer in land use sectors offers new opportunities for adaptation, mitigation,**
27 **international cooperation, R&D collaboration, and local engagement (*medium confidence*).**
28 International cooperation to modernise the traditional biomass sector will free up both land and labour
29 for more productive uses. Technology transfer can assist the measurement and accounting of emission
30 reductions by developing countries. {7.4.4, 7.4.6}

31
32 **Measuring progress towards goals is important in decision-making and adaptive governance to**
33 **create common understanding and advance policy effectiveness (*high agreement, medium***
34 ***evidence*).** Measurable indicators, selected with the participation of people and supporting data
35 collection, are useful for climate policy development and decision-making. Indicators include the
36 SDGs, nationally determined contributions (NDCs), land degradation neutrality (LDN) core
37 indicators, carbon stock measurement, measurement and monitoring for REDD+, metrics for
38 measuring biodiversity and ecosystem services, and governance capacity. {7.5.5, 7.5.7, 7.6.4, 7.6.6}

39
40 **The complex spatial, cultural and temporal dynamics of risk and uncertainty in relation to land**
41 **and climate interactions and food security, require a flexible, adaptive, iterative approach to**
42 **assessing risks, revising decisions and policy instruments (*high confidence*).** Adaptive, iterative
43 decision making moves beyond standard economic appraisal techniques to new methods such as
44 dynamic adaptation pathways with risks identified by trigger points through indicators. Scenarios can
45 provide valuable information at all planning stages in relation to land, climate and food; adaptive
46 management addresses uncertainty in scenario planning with pathway choices made and reassessed to
47 respond to new information and data as it becomes available. {3.7.5, 7.4.4, 7.5.2, 7.5.3, 7.5.4, 7.5.7,
48 7.6.1, 7.6.3}

1 **Indigenous and local knowledge (ILK) can play a key role in understanding climate processes**
2 **and impacts, adaptation to climate change, sustainable land management across different**
3 **ecosystems, and enhancement of food security** (*high confidence*). ILK is context-specific,
4 collective, informally transmitted, and multi-functional, and can encompass factual information about
5 the environment and guidance on management of resources and related rights and social behaviour.
6 ILK can be used in decision-making at various scales and levels, and exchange of experiences with
7 adaptation and mitigation that include ILK is both a requirement and an entry strategy for
8 participatory climate communication and action. Opportunities exist for integration of ILK with
9 scientific knowledge. {7.4.1, 7.4.5, 7.4.6, 7.6.4, Cross-Chapter Box 13: in this chapter}

10
11 **Participation of people in land and climate decision making and policy formation allows for**
12 **transparent effective solutions and the implementation of response options that advance**
13 **synergies, reduce trade-offs in sustainable land management** (*high confidence*), **and overcomes**
14 **barriers to adaptation and mitigation** (*high confidence*). Improvements to sustainable land
15 management are achieved by: (1) engaging people in citizen science by mediating and facilitating
16 landscape conservation planning, policy choice, and early warning systems (*medium confidence*); (2)
17 involving people in identifying problems (including species decline, habitat loss, land use change in
18 agriculture, food production and forestry), selection of indicators, collection of climate data, land
19 modelling, agricultural innovation opportunities. When social learning is combined with collective
20 action, transformative change can occur addressing tenure issues and changing land use practices
21 (*medium confidence*). Meaningful participation overcomes barriers by opening up policy and science
22 surrounding climate and land decisions to inclusive discussion that promotes alternatives. {3.7.5,
23 7.4.1, 7.4.9; 7.5.1, 7.5.4, 7.5.5, 7.5.7, 7.6.4, 7.6.6}

24
25 **Empowering women can bolster synergies among household food security and sustainable land**
26 **management** (*high confidence*). This can be achieved with policy instruments that account for
27 gender differences. The overwhelming presence of women in many land based activities including
28 agriculture provides opportunities to mainstream gender policies, overcome gender barriers, enhance
29 gender equality, and increase sustainable land management and food security (*high confidence*).
30 Policies that address barriers include gender qualifying criteria and gender appropriate delivery,
31 including access to financing, information, technology, government transfers, training, and extension
32 may be built into existing women's programs, structures (civil society groups) including collective
33 micro enterprise (*medium confidence*) . {Cross-Chapter Box 11 in this chapter}

34
35 **The significant social and political changes required for sustainable land use, reductions in**
36 **demand and land-based mitigation efforts associated with climate stabilisation require a wide**
37 **range of governance mechanisms.** The expansion and diversification of land use and biomass
38 systems and markets requires hybrid governance: public-private partnerships, transnational,
39 polycentric, and state governance to insure opportunities are maximised, trade-offs are managed
40 equitably and negative impacts are minimised (*medium confidence*). {7.4.6, 7.6.2, 7.6.3, Cross-
41 Chapter Box 7 in Chapter 6}

42
43 **Land tenure systems have implications for both adaptation and mitigation, which need to be**
44 **understood within specific socio-economic and legal contexts, and may themselves be impacted**
45 **by climate change and climate action** (*limited evidence, high agreement*). Land policy (in a
46 diversity of forms beyond focus on freehold title) can provide routes to land security and facilitate or
47 constrain climate action, across cropping, rangeland, forest, fresh-water ecosystems and other
48 systems. Large-scale land acquisitions are an important context for the relations between tenure
49 security and climate change, but their scale, nature and implications are imperfectly understood. There
50 is *medium confidence* that land titling and recognition programs, particularly those that authorize and

1 respect indigenous and communal tenure, can lead to improved management of forests, including for
2 carbon storage. Strong public coordination (government and public administration) can integrate land
3 policy with national policies on adaptation and reduce sensitivities to climate change. {7.6.2; 7.6.3;
4 7.6.4, 7.6.5}

5
6 **Significant gaps in knowledge exist when it comes to understanding the effectiveness of policy**
7 **instruments and institutions related to land use management, forestry, agriculture and**
8 **bioenergy. Interdisciplinary research is needed on the impacts of policies and measures in land**
9 **sectors.** Knowledge gaps are due in part to the highly contextual and local nature of land and climate
10 measures and the long time periods needed to evaluate land use change in its socio-economic frame,
11 as compared to technological investments in energy or industry that are somewhat more comparable.
12 Significant investment is needed in monitoring, evaluation and assessment of policy impacts across
13 different sectors and levels. {7.7}

14
15

7.1. Introduction and Relation to Other Chapters

Land is integral to human habitation and livelihoods, providing food and resources, and also serves as a source of identity and cultural meaning. However, the combined impacts of climate change, desertification, land degradation and food insecurity pose obstacles to resilient development and the achievement of the Sustainable Development Goals (SDGs). This chapter reviews and assesses literature on risk and uncertainty surrounding land and climate change, policy instruments and decision-making addressing those risks and uncertainty, and governance practices that advance response options with co-benefits identified in Chapter 6, lessen the socio-economic impacts of climate change and reduce trade-offs, and advance sustainable land management.

7.1.1. Findings of Previous IPCC Assessments and Reports

This chapter builds on earlier assessments contained in several chapters of the IPCC Fifth Assessment Report (the contributions of both Working Groups II and III), the IPCC Special Report on Managing the Risks of Extreme Events and Disasters to Advance Climate Change Adaptation (SREX)(IPCC 2012), and the IPCC Special Report on Global Warming of 1.5°C (SR15). (IPCC 2018a) The findings most relevant to decision-making on and governance of responses to land-climate challenges are set out in Box 7.1.

Box 7.1 Relevant Findings of Recent IPCC Reports

Climate change and sustainable development pathways

“Climate change poses a moderate threat to current sustainable development and a severe threat to future sustainable development” (Denton et al. 2014; Fleurbaey et al. 2014).

Significant transformations may be required for climate-resilient pathways (Denton et al. 2014; Jones et al. 2014).

The design of climate policy is influenced by: (1) differing ways that individuals and organisations perceive risks and uncertainties; (2) the consideration of a diverse array of risks and uncertainties as well as human and social responses which may be difficult to measure, are of low probability but which would have a significant impact if they occurred (Kunreuther et al. 2014; Fleurbaey et al. 2014; Kolstad et al. 2014).

Building climate resilient pathways requires iterative, continually evolving and complementary processes at all levels of government (Denton et al. 2014; Kunreuther et al. 2014; Kolstad et al. 2014; Somanthan et al. 2014; Lavell et al. 2012).

Important aspects of climate resilient policies include local level institutions, decentralisation, participatory governance, iterative learning, integration of local knowledge, and reduction of inequality (Dasgupta et al. 2014; Lavell et al. 2012; Cutter et al. 2012b; O’ Brien et al. 2012; Roy et al. 2018).

Climate action and sustainable development are linked: adaptation has co-benefits for sustainable development while “sustainable development supports, and often enables, the fundamental societal and systems transitions and transformations that help limit global warming” (IPCC 2018b). Redistributive policies that shield the poor and vulnerable can resolve trade-offs between mitigation objectives and the hunger, poverty and energy access SDGs.

Land and rural livelihoods

Policies and institutions relating to land, including land tenure, can contribute to the vulnerability of rural people, and constrain adaptation. Climate policies, such as encouraging cultivation of biofuels,

1 or payments under REDD+, will have significant secondary impacts, both positive and negative, in
2 some rural areas (Dasgupta et al. 2014).

3 “Sustainable land management is an effective disaster risk reduction tool”(Cutter et al. 2012a).

4 **Risk and risk management**

5 A variety of emergent risks not previously assessed or recognised, can be identified by taking into
6 account: a) the “interactions of climate change impacts on one sector with changes in exposure and
7 vulnerability, as well as adaptation and mitigation actions”, and; b) “indirect, trans-boundary, and
8 long-distance impacts of climate change” including price spikes, migration, conflict and the
9 unforeseen impacts of mitigation measures (Oppenheimer et al. 2014)

10 “Under any plausible scenario for mitigation and adaptation, some degree of risk from residual
11 damages is unavoidable” (Oppenheimer et al. 2014).

12 **Decision-making**

13 “Risk management provides a useful framework for most climate change decision-making. Iterative
14 risk management is most suitable in situations characterised by large uncertainties, long time frames,
15 the potential for learning over time, and the influence of both climate as well as other socioeconomic
16 and biophysical changes” (Jones et al. 2014).

17 “Decision support is situated at the intersection of data provision, expert knowledge, and human
18 decision making at a range of scales from the individual to the organisation and institution” (Jones et
19 al. 2014).

20 “Scenarios are a key tool for addressing uncertainty”, either through problem exploration or solution
21 exploration (Jones et al. 2014).

22 **Governance**

23 There is no single approach to adaptation planning and both top-down and bottom-up approaches are
24 widely recognised. “Institutional dimensions in adaptation governance play a key role in promoting
25 the transition from planning to implementation of adaptation” (Mimura et al. 2014). Adaptation is also
26 essential at all scales, including adaptation by local governments, businesses, communities, and
27 individuals (Denton et al. 2014).

28 “Strengthened multi-level governance, institutional capacity, policy instruments, technological
29 innovation and transfer and mobilisation of finance, and changes in human behaviour and lifestyles
30 are enabling conditions that enhance the feasibility of mitigation and adaptation options for 1.5°C –
31 consistent systems transitions” (IPCC 2018b).

32 Governance is key for vulnerability and exposure represented by institutionalised rule systems and
33 habituated behaviour and norms that govern society and guide actors and , “it is essential to improve
34 knowledge on how to promote adaptive governance within the framework of risk assessment and risk
35 management” (Cardona 2012).

36

37 **7.1.2. Treatment of Key Terms in the Chapter**

38 While the term risk continues to be subject to a growing number of definitions in different disciplines
39 and sectors, this chapter takes as a starting point the definition used in the IPCC Special Report on
40 Global Warming of 1.5°C (SR15) (IPCC 2018a), which reflects definitions used by both Working
41 Group II and Working Group III in the Fifth Assessment Report (AR5): “The potential for adverse
42 consequences where something of value is at stake and where the occurrence and degree of an
43 outcome is uncertain” (Allwood et al. 2014; Oppenheimer et al. 2014). The SR15 definition further
44 specifies: “In the context of the assessment of climate impacts, the term risk is often used to refer to
45 the potential for adverse consequences of a climate-related hazard, or of adaptation or mitigation
46 responses to such a hazard, on lives, livelihoods, health and wellbeing, ecosystems and species,

1 economic, social and cultural assets, services (including ecosystem services), and infrastructure”. In
2 SR15, as in the IPCC SREX and AR5 WGII, risk is conceptualised as resulting from the interaction of
3 vulnerability (of the affected system), its exposure over time (to a hazard), as well as the (climate-
4 related) impact and the likelihood of its occurrence (AR5 2014; IPCC 2018a, 2012). In the context of
5 SRCCL, risk must also be seen as including risks to the implementation of responses to land-climate
6 challenges from economic, political and governance factors. Climate and land risks must be seen in
7 relation to human values and objectives (Denton et al. 2014). Risk is closely associated with concepts
8 of vulnerability and resilience, which are themselves subject to differing definitions across different
9 knowledge communities.

10 Risks examined in this chapter arise from more than one of the major land-climate-society challenges
11 (desertification, land degradation, and food insecurity), or partly stem from mitigation or adaptation
12 actions, or cascade across different sectors or geographical locations. They could thus be seen as
13 examples of *emergent risks* (Oppenheimer et al. 2014, p. 1052): “aris[ing] from the interaction of
14 phenomena in a complex system”. Stranded assets in the coal sector due to proliferation of renewable
15 energy and government response could be examples of emergent risks (Saluja, N and Singh 2018;
16 Marcacci 2018). Additionally, the absence of an explicit goal for conserving fresh-water ecosystems
17 and ecosystem services in SDGs (in contrast to a goal (Life Under Water) that is exclusively for
18 marine biodiversity) is related to its trade-offs with energy and irrigation goals thus posing a
19 substantive risk (Nilsson et al. 2016b; Vörösmarty et al. 2010).

20 *Governance* is not previously well defined in IPCC reports, but is used here to include all of the
21 processes, structures, rules and traditions that govern, which may be undertaken by actors including
22 governments, markets, organisations, or families (Bevir 2011), with particular reference to the
23 multitude of actors operating in respect of land and climate interactions. Such definitions of
24 governance allow for it to be decoupled from the more familiar concept of government and studied in
25 the context of complex human-environment relations and environmental and resource regimes (Young
26 2017a). Governance involves the interactions among formal and informal institutions through which
27 people articulate their interests, exercise their legal rights, meet their legal obligations, and mediate
28 their differences (UNDP 1997).

29 **7.1.3. Roadmap to the chapter**

30 This chapter firstly discusses risks and their drivers, at various scales, in relation to land-climate
31 challenges, including risks associated with responses to climate change (Section 7.2). The
32 consequences of the principal risks in economic and human terms, and associated concepts such as
33 tipping points and windows of opportunity for response are then described (Section 7.3). Policy
34 responses at different scales to different land-climate risks, and barriers to implementation, are
35 described in Section 7.4, followed by assessment of approaches to decision-making on land-climate
36 challenges (Section 7.5), and questions of the governance of the land-climate interface (Section 7.6).
37 Key uncertainties and knowledge gaps are identified (Section 7.7).

38 **7.2. Climate-related risks for land-based human systems and** 39 **ecosystems**

40 This section examines risks that climate change pose to selected land-based human systems and
41 ecosystems, and then further explores how social and economic choices, as well as responses to
42 climate change, will exacerbate or lessen risks. Risk is the potential for adverse consequences for
43 human or ecological systems, recognising the diversity of values and objectives associated with such
44 systems. The interacting processes of climate change, land change, and unprecedented social and
45 technological change, pose significant risk to climate resilient sustainable development. The pace,
46 intensity, and scale of these sizeable risks affect the central issues in sustainable development: access
47 to ecosystem services and resources essential to sustain people in given locations, how and where

1 people live and work, and the means to safeguard human wellbeing against disruptions (Warner et al.
2 2019). In the context of climate change, adverse consequences can arise from the potential *impacts of*
3 climate change as well as human *responses to* climate change. Relevant adverse consequences include
4 those on lives, livelihoods, health and wellbeing, economic, social and cultural assets and
5 investments, infrastructure, services (including ecosystem services), ecosystems and species (see
6 Glossary). Risks result from dynamic interactions between climate-related hazards with the exposure
7 and vulnerability of the affected human or ecological system to the hazards. Hazards, exposure and
8 vulnerability may change over time and space as a result of socio-economic changes and human
9 decision-making (*risk management*). Numerous uncertainties exist in the scientific understanding of
10 risk (See Chapter 1.2.2).

11 **7.2.1. Assessing Risk**

12 This chapter applies and further improves methods used in previous IPCC reports including AR5 and
13 the Special Report on Global Warming of 1.5° (SR15) to assess risks. Evidence is drawn from
14 published studies, which include observations of impacts from human-induced climate change and
15 model projections for future climate change. Such projections are based on IAMs, ESMs, regional
16 climate models and global or regional impact models examining the impact of climate change on
17 various indicators (see Cross-Chapter Box 1: Scenarios, in Chapter 1). Results of laboratory and field
18 experiments that examine impacts of specific changes were also included in the review. Risks under
19 differed future socio-economic conditions were assessed using recent publications based on Shared
20 Socio-economic pathways (SSPs). SSPs provide storylines about future socio-economic development
21 and can be combined with RCPs (Riahi et al. 2017)(see Cross-Chapter Box 9: Illustrative climate and
22 land pathways, in Chapter 6). Risk arising from land-based mitigation and adaptation choices is
23 assessed using studies examining the adverse side-effects of such responses (7.2.3).

24
25 Burning embers figures introduced in the IPCC Third Assessment Report through to the Fifth
26 Assessment Report, and the SR15, were developed for this report to illustrate risks at different
27 temperature thresholds. Key components involved in desertification, land degradation and food
28 security were identified based on discussions with authors in Chapter 3 –5. The final list of burning
29 embers in Figure 7.1 is not intended to be fully comprehensive, but represents processes for which
30 sufficient literature exists to make expert judgements. Literature used in the burning embers
31 assessment is summarised in table(s) in supplementary material. Following an approach articulated in
32 O’Neill et al. (2017), expert judgements were made to assess thresholds of risk (O’Neill et al. 2017a).
33 To further strengthen replicability of the method, a predefined protocol based on a modified Delphi
34 process was followed (Mukherjee et al. 2015). This included two separate anonymous rating rounds,
35 feedback in between rounds and a group discussion to achieve consensus.

36
37 Burning embers provide ranges of a given variable (typically global mean near-surface air
38 temperature) for which risks transitions from one risk category to the next. Four categories are
39 considered: undetectable, moderate, high and very high. Moderate risk indicates that impacts are
40 detectable and attributable to climate-related factors. High risk indicates widespread impacts on larger
41 number or proportion of population/ area but with the potential to adapt or recover. Very high risk
42 indicates severe and possibly irreversible impacts with limited ability of societies and ecosystems to
43 adapt to them. Transitions between risk categories were assigned confidence levels based on the
44 amount, and quality, of academic literature supporting judgements: L= Low, M = Medium, and H =
45 High. Further details of the procedure is provided in supplementary material.

46 47 **7.2.2. Risks to land systems arising from climate change**

48 At current levels of global mean surface temperature (GMST) increase, impacts are already detectable
49 across numerous land-related systems (*high confidence*) (see chapters 2, 3, 4, 6). There is *high*
50 *confidence* that unabated future climate change will result in continued changes to processes involved
51 in desertification, land degradation and food security, including: water scarcity in drylands, soil
52 erosion, coastal degradation, vegetation loss, fire, permafrost thaw as well as access, stability,

1 utilisation and physical availability of food (Figure 7.1). These changes will increase risks to food
 2 systems, the health of humans and ecosystems, livelihoods, the value of land, infrastructure and
 3 communities (7.3). Details of the risks, and their transitions, are described in the following
 4 subsections.
 5

6
 7
 8 **Figure 7.1: Risks to selected land system elements as a function of global mean surface temperature**
 9 **increase since pre-industrial times. Impacts on human and ecological systems include: 1) economic loss**
 10 **and declines in livelihoods and ecosystem services from water scarcity in drylands, 2) damage to natural**
 11 **and built environment from permafrost thaw related ground instability, 3) damage to infrastructure,**
 12 **altered land cover, accelerated erosion and increased air pollution from fires, 4) vegetation loss and shifts**
 13 **in vegetation structure, 5) economic loss and declines in livelihoods and ecosystem services from reduced**
 14 **land productivity due to soil erosion, 6) increased disruption of food supply (stability), 7) increased**
 15 **disruption of food access and 8) changes to crop yield and food availability in low-latitude regions. Risks**
 16 **are global (3,4,5,6,7) and specific to certain regions (1,2,8). Selected components are illustrative and not**
 17 **intended to be fully comprehensive of factors influencing food security, land degradation and**
 18 **desertification. The supporting literature is provided in Supplementary Material.**
 19
 20

21 7.2.2.1. Crop yield in low latitudes

22 There is *high confidence* that climate change has resulted in decreases in yield (of wheat, rice, maize,
 23 soy) and reduced food availability in low-latitude regions (IPCC, 2018, 5.2.2). Countries in low-
 24 latitude regions are particularly vulnerable because the livelihoods of high proportions of the
 25 population are dependent on agricultural production. Even moderate temperature increases (1°C to 2
 26 °C) have negative yield impacts for major cereals, because the climate of many tropical agricultural
 27 regions is already quite close to the high temperature thresholds for suitable production of these cereal
 28 (Rosenzweig et al. 2014). Thus, by 1.5°C GMT, or between approximately 1.6°C and approximately
 29 2.6°C of local warming, risks to yields may already transition to high in West Africa, Southeast Asia
 30 and Central and South America (Faye et al. 2018) (*medium confidence*). For further information see
 31 5.3.2.1. By contrast, higher latitudes may initially benefit from warming as well as well higher CO₂
 32 concentrations (IPCC 2018a). Wheat yield losses are expected to be lower for the United States (−5.5
 33 ± 4.4% per degree Celsius) and France (−6.0 ± 4.2% per degree Celsius) compared to India (−9.1 ±
 34 5.4% per degree Celsius) (Zhao et al. 2017). Very high risks to low latitude yields may occur between
 35 3°C and 4°C (*medium confidence*). At these temperatures, catastrophic reductions in crop yields may
 36 occur, of up to 60% in low latitudes (Rosenzweig et al. 2014)(5.2.2, 5.2.3). Some studies report
 37 significant population displacement from the tropics related to systemic livelihood disruption in
 38 agriculture systems (Tittonell 2014; Montaña et al. 2016; Huber-Sannwald et al. 2012; Wise et al.
 39 2016; Tanner et al. 2015; Mohapatra 2013). However, at higher temperatures of warming, all regions
 40 of the world face risks of declining yields as a result of extreme weather events and reduced heat
 41 tolerance of maize, rice, wheat and soy (Zhao et al. 2017; IPCC 2018a).
 42

7.2.2.2. Stability of and access to food supplies

Stability of food supply is expected to decrease as the magnitude and frequency of extreme events increase, disrupting food chains in all areas of the world (Wheeler and Von Braun 2013; Coates 2013; Puma et al. 2015; Deryng et al. 2014; Harvey et al. 2014b; Iizumi et al. 2013; Seaman et al. 2014)(*medium evidence, high agreement*)(5.3.2, 5.3.3, 5.6.2, 5.7.1). While international trade in food is assumed to be a key response for alleviating hunger, historical data and economic models suggest that international trade does not adequately redistribute food globally to offset yield declines or other food shortages when weather extremes reduce crop yields (Schmitz et al. 2012; Chatzopoulos et al. 2019; Marchand et al. 2016; Gilbert 2010; Wellesley et al. 2017) (*medium confidence*). When droughts, heat waves, floods or other extremes destroy crops, evidence has shown key producing countries have constrained exports contributing to price spikes and social tension in importing countries which reduces access to food (von Uexkull et al. 2016; Gleick 2014; Maystadt and Ecker 2014; Kelley et al. 2015; Church et al. 2017; Götz et al. 2013; Puma et al. 2015; Willenbockel 2012; Headey 2011; Distefano et al. 2018; Brooks 2014)(*medium evidence, medium agreement*). There is little understanding of how food system shocks cascade through a modern interconnected economy. Reliance on global markets may reduce some risks, but the on-going globalisation of food trade networks exposes the world food system to new impacts that have not been seen in the past (5.1.2, 5.2.1, 5.5.2.5, 5.6.5, 5.7.1). The global food system is vulnerable to systemic disruptions and increasingly interconnected inter-country food dependencies and changes in frequency and severity of extreme weather events may complicate future responses(Puma et al. 2015; Jones and Hiller 2017).

Impacts of climate change are already detectable on food supply and access as price and trade reactions have occurred in response to heat waves, droughts and other extreme events (Noble et al. 2014; O'Neill et al. 2017b)(*high evidence, high agreement*). The impact of climate change on food stability is underexplored (Schleussner et al. 2016; James et al. 2017). However, some literature assesses that by about 2035, daily maximum temperatures will exceed the 90th percentile of historical (1961–1990) temperatures on 25–30% of days (O'Neill et al. 2017b)(ref 35, Figs 11–17) with negative shocks to food stability and world food prices. O'Neill et al. (2017b) remark that in the future, return periods for precipitation events globally (land only) will reduce from one-in-20-year (historical) to about once-in-14-year or less by 2046–2065 in many areas of the world. Domestic efforts to insulate populations from food price spikes associated with climatic stressors in the mid-2000s have been shown to inadequately shield from poverty, and worsen poverty globally (Diffenbaugh et al. 2012; Meyfroidt et al. 2013; Hertel et al. 2010). The transition to high risk is estimated to occur around 1.4°C, possibly by 2035, due to changes in temperature and heavy precipitation events (*medium confidence*) (O'Neill et al. 2017b; Fritsche et al. 2017a; Harvey et al. 2014b). Very high risk may occur by 2.4°C (*medium confidence*) and 4°C of warming is considered catastrophic (IPCC 2018c; Noble et al. 2014) for food stability and access because a combination of extreme events, compounding political and social factors, and shocks to crop yields can heavily constrain options to ensure food security in import-reliant countries.

7.2.2.3. Soil Erosion

Soil erosion increases risks of economic loss and declines in livelihoods due to reduced land productivity. In the EU, on-site costs of soil erosion by wind has been reported at an average of 55 USD per hectare annually, but up to USD 450 per hectare for sugar beet and oilseed rape (Middleton et al. 2017)). Farmers in the Dapo watershed in Ethiopia lose about USD 220 per hectare of maize due to loss of nitrogen through soil erosion (Erkossa et al. 2015). Soil erosion not only increases crop loss but has been shown to have negative household feeding, with older farmers most vulnerable to losses from erosion (Ighodaro et al. 2016). Erosion also results in increased risks to human health, through air pollution from aerosols (Middleton et al. 2017), and brings risks of reduced ecosystem services including supporting services related to soil formation.

1
2 At current levels of warming, changes in erosion are already detected in many regions. Attribution to
3 climate change is challenging as there are other powerful drivers of erosion (e.g., land use), limited
4 global-scale studies (Li and Fang 2016a; Vanmaercke et al. 2016a) and the absence of formal
5 detection and attribution studies (4.2.3). However, studies have found an increase in short-duration
6 and intensity precipitation, due to anthropogenic climate change, which is a causative factor for soil
7 erosion (Lenderink and van Meijgaard 2008; Li and Fang 2016b). High risks of erosion may occur
8 between 2° and 3.5° (*low confidence*) as continued increases in intense precipitation is projected at
9 these temperature thresholds (Fischer and Knutti 2015) in many regions. Warming also reduces soil
10 organic matter, diminishing resistance against erosion. There is *low confidence* concerning the
11 temperature threshold at which risks become very high due to large regional differences and limited
12 global-scale studies (Li and Fang 2016b; Vanmaercke et al. 2016b) (4.4).

13 14 **7.2.2.4. Dryland water scarcity**

15 Water scarcity in drylands contributes to changes in desertification and hazards such as dust storms,
16 increasing risks of economic loss, declines in livelihoods of communities and negative health effects
17 (*high confidence*) (3.1.3). Further information specific to costs and impacts of water scarcity and
18 droughts is detailed in Cross-Chapter Box 5: Case study on policy response to drought, in Chapter 3.

19
20 The IPCC AR5 report and the SR15 concluded that there is *low confidence* in the direction of drought
21 trends since 1950 at the global scale. While these reports did not assess water scarcity with a specific
22 focus on drylands, they indicated that there is *high confidence* in observed drought increases in some
23 regions of the world, including in the Mediterranean and West Africa (IPCC AR5) and that there is
24 *medium confidence* that anthropogenic climate change has contributed to increased drying in the
25 Mediterranean region (including southern Europe, northern Africa and the Near East) and that this
26 tendency will continue to increase under higher levels of global warming (IPCC 2018d). Some parts
27 of the drylands have experienced decreasing precipitation over recent decades (IPCC AR5; Chapter 3,
28 3.2), consistent with the fact that climate change is implicated in desertification trends in some regions
29 (3.2.2). Dust storms, linked to changes in precipitation and vegetation, appear to be occurring with
30 greater frequency in some deserts and their margins (Goudie 2014) (3.3.1). There is therefore *high*
31 *confidence* that the transition from undetectable to moderate risk associated with water scarcity in
32 drylands occurred in recent decades in the range 0.7°C to 1°C (Fig. 7.1).

33
34 Between 1.5°C and 2.5°C, the risk level is expected to increase from moderate to high (*medium*
35 *confidence*). Globally, at 2°C an additional 8% of the world population (of population in 2000) will be
36 exposed to new or aggravated water scarcity (IPCC 2018d). However, at 2°C, the annual warming
37 over drylands will reach 3.2°C–4.0°C, implying about 44% more warming over drylands than humid
38 lands (Huang et al. 2017), thus potentially aggravating water scarcity issues through increased
39 evaporative demand. (Byers et al. 2018a) estimate that 3–22% of the drylands population (range
40 depending on socio-economic conditions) will be exposed and vulnerable to water stress. The
41 Mediterranean, North Africa and the Levant will be particularly vulnerable to water shortages and
42 expansion of desert terrain and vegetation is predicted to occur in the Mediterranean biome, an
43 unparalleled change in the last 10,000 years (*medium confidence*) (IPCC 2018d). At 2.5°C–3.5°C
44 risks are expected to become very high with migration from some drylands resulting as the only
45 adaptation option (*medium confidence*). Scarcity of water for irrigation is expected to increase, in
46 particular in Mediterranean regions, with limited possibilities for adaptation (Haddeland et al. 2014).

47 48 **7.2.2.5. Vegetation degradation**

49 There are clear links between climate change and vegetation cover changes, tree mortality, forest
50 diseases, insect outbreaks, forest fires, forest productivity and net ecosystem biome production (Allen
51 et al. 2010; Bentz et al. 2010; Anderegg et al. 2013; Hember et al. 2017; Song et al. 2018; Sturrock et
52 al. 2011). Forest dieback, often a result of drought and temperature changes, not only produces risks
53 to forest ecosystems but also to people with livelihoods dependent on forests. A 50 year study of
54 temperate forest, dominated by beech (*Fagus sylvatica* L.), documented a 33% decline in basal area

1 and 70% decline in juvenile tree species, possibly as a result of interacting pressures of drought,
2 overgrazing and pathogens (Martin et al. 2015). There is *high confidence* that such dieback impacts
3 ecosystem properties and services including soil microbial community structure (Gazol et al. 2018).
4 Forest managers and users have reported negative emotional impacts from forest dieback such as
5 pessimism about losses, hopelessness, and fear (Oakes et al. 2016). Practices and policies such as
6 forest classification systems, projection of growth, yield and models for timber supply are already
7 being affected by climate change (Sturrock et al. 2011).

8
9 While risks to ecosystems and livelihoods from vegetation degradation are already detectable at
10 current levels of GMT increase, risks are expected to reach high levels between 1.6°C and 2.6°C
11 (*medium confidence*). Significant uncertainty exists due to countervailing factors: CO₂ fertilisation
12 encourages forest expansion but increased drought, insect outbreaks, and fires result in dieback
13 (Bonan 2008; Lindner et al. 2010). The combined effects of temperature and precipitation change,
14 with CO₂ fertilisation, make future risks to forests very location specific. It is challenging therefore to
15 make global estimates. However, even locally specific studies make clear that very high risks occur
16 between 2.6°C and 4°C (*medium confidence*). Australian tropical rainforests experience significant
17 loss of biodiversity with 3.5°C increase. There are no areas with greater than 30 species and all
18 endemics disappear from low and mid-elevation regions (Williams et al. 2003). Mountain ecosystems
19 are particularly vulnerable (Loarie et al. 2009).

20 21 **7.2.2.6. Fire damage**

22 Increasing fires result in heightened risks to infrastructure, accelerated erosion, altered hydrology,
23 increased air pollution, and negative mental health impacts. Fire not only destroys property but
24 induces changes in underlying site conditions (ground cover, soil water repellency, aggregate stability
25 and surface roughness) which amplifies runoff and erosion, increasing future risks to property and
26 human lives during extreme rainfall events (Pierson and Williams 2016). Dust and ash from fires can
27 impact air quality in a wide area. For example, a dust plume from a fire in Idaho, USA, in September
28 2010 was visible in MODIS satellite imagery and extended at least 100 km downwind of the source
29 area (Wagenbrenner et al. 2013). Individuals can suffer from property damage or direct injury,
30 psychological trauma, depression, post traumatic stress disorder and have reported negative impacts to
31 well being from loss of connection to landscape (Paveglio et al. 2016; Sharples et al. 2016a). Costs of
32 large wildfires in the United States can exceed USD 20 million a day (Pierson et al. 2011) and has
33 been estimated at USD8.5 billion per year in Australia (Sharples et al. 2016b). Globally, human
34 exposure to fire will increase due to projected population growth in fire-prone regions (Knorr et al.
35 2016a).

36
37 It is not clear how quickly, or even if, systems can recover from fires. Longevity of effects may differ
38 depending on cover recruitment rate and soil conditions, recovering in one to two seasons or over ten
39 growing seasons (Pierson et al. 2011). In Russia, one third of forest area affected by fires turned into
40 unproductive areas where natural reforestation is not possible within 2–3 life cycles of major forest
41 forming species (i.e., 300–600 years) (Shvidenko et al. 2012).

42
43 Risks under current warming levels are already moderate as anthropogenic climate change has caused
44 significant increases in fire area (*high confidence*) due to availability of detection and attribution
45 studies) (Cross-Chapter Box 3: Fire and climate change, in Chapter 2). This has been detected and
46 attributed regionally, notably in Western US (Abatzoglou and Williams 2016; Westerling et al. 2006;
47 Dennison et al. 2014), Indonesia (Fernandes et al. 2017) and other regions (Jolly et al. 2015).
48 Regional increases have been observed despite a global-average declining trend induced by human
49 fire suppression strategies especially in savannas (Yang et al. 2014a; Andela et al. 2017).

50
51 High risks of fire may occur between 1.3°C and 1.7°C (*medium confidence*). Studies note heightened
52 risks as “fire weather” and land prone to fire increase above 1.5°C (Abatzoglou et al. 2019a), with
53 *medium confidence* in this transition, due to complex interplay between (i) global warming (ii) CO₂-
54 fertilisation, and (iii) human/economic factors affecting fire risk. Canada, the USA and Mediterranean

1 may be particularly vulnerable as the combination of increased fuel due to CO₂ fertilisation, and
2 weather conditions conducive to fire increase risks to people and property. Some studies show
3 substantial effects at 3°C (Knorr et al. 2016b; Abatzoglou et al. 2019b), indicating a transition to very
4 high risks (*medium confidence*). At high warming levels, climate change may become the primary
5 driver of fire risk in the extratropics (Knorr et al. 2016b; Abatzoglou et al. 2019b; Yang et al. 2014b).
6 Pyroconvection activity may increase, in areas such as southeast Australia (Dowdy and Pepler 2018),
7 posing major challenges to adaptation.
8

9 **7.2.2.7. Permafrost**

10 There is a risk of damage to natural and built environment from permafrost thaw related ground
11 instability. Residential, transportation, and industrial infrastructure in the pan-Arctic permafrost area
12 are particularly at risk (Hjort et al., 2018). High risks already exist at low temperatures (*high*
13 *confidence*). Approximately, 21–37% of Arctic permafrost is projected to thaw under 1.5°C of
14 warming (Hoegh-Guldberg et al., 2018). This increases to very high risk around 2°C (between 1.8 and
15 2.3°C) of temperature increase since pre-industrial times (*medium confidence*) with 35–47% of the
16 Arctic permafrost thawing (Hoegh-Guldberg et al., 2018). If climate stabilised at 2°C, still
17 approximately 40% of permafrost area would be lost (Chadburn et al., 2017), leading to nearly four
18 million people and 70% of current infrastructure in the pan-Arctic permafrost area exposed to
19 permafrost thaw and high hazard (Hjort et al., 2018). Indeed between 2°C and 3°C a collapse of
20 permafrost may occur with a drastic biome shift from tundra to boreal forest (Drijfhout et al. 2015;
21 SR15). There is mixed evidence of a tipping point in permafrost collapse, leading to enhanced
22 greenhouse gas emission and particularly methane, between 2°C and 3°C (Hoegh-Guldberg et al.,
23 2018).
24

25 **7.2.2.8. Risks of desertification, land degradation and food insecurity under** 26 **different Future Development Pathways**

27 Socio-economic developments and policy choices that govern land-climate interactions are an
28 important driver of risk along with climate change (*very high confidence*). Risks under two different
29 Shared Socio-economic Pathways (SSPs) were assessed using emerging literature. SSP1 is
30 characterised by low population growth, reduced inequalities, land-use regulation, low meat
31 consumption, and moderate trade (Riahi et al. 2017; Popp et al. 2017a). SSP3 is characterised by high
32 population growth, higher inequalities, limited land-use regulation, resource-intensive consumption
33 including meat-intensive diets, and constrained trade (for further details see Chapter 1 and Cross-
34 Chapter Box 9: Illustrative climate and land pathways in Chapter 6). These two SSPs, among the set
35 of five SSPs, were selected because they illustrate contrasting futures, ranging from low (SSP1) to
36 high (SSP3) challenges to mitigation and adaptation. Figure 7.2 shows that for a given global mean
37 temperature change, risks are different under SSP1 compared to SSP3. In SSP1, global temperature
38 change does not increase above 3°C even in the baseline case (i.e., with no additional mitigation
39 measures) because in this pathway the combination of low population and autonomous improvements,
40 for example, in terms of carbon intensity and/or energy intensity, effectively act as mitigation
41 measures (Riahi et al., 2017). Thus Figure 7.2 does not indicate risks beyond this point in either SSP1
42 and SSP3. Literature based on such socio-economic and climate models is still emerging and there is a
43 need for greater research on impacts of different pathways. There are few SSP studies exploring
44 aspects of desertification and land degradation, but a greater number of SSP studies on food security
45 (see supplementary material). SSP1 reduces the vulnerability and exposure of human and natural
46 systems and thus limits risks resulting from desertification, land degradation and food insecurity
47 compared to SSP3 (*high confidence*).
48
49
50
51

Figure 7.2: Risks associated with desertification, land degradation and food security as a function of climate change and level of socio-economic development. Increasing risks associated to desertification include a growing fraction of population exposed and vulnerable to water scarcity and changes in irrigation supply and demand. Risks related to land degradation include increased vegetation loss, population exposed to fire and floods, costs of floods, extent of deforestation, and ecosystem services including the ability of land to sequester carbon. Risks to food security include population at risk of hunger, food price increases, increases in disability adjusted life years. The risks are assessed for two contrasted socio-economic futures (SSP1 and SSP3) under unmitigated climate change {3.5; 4.2.1.2; 5.2.2; 5.2.3; 5.2.4; 5.2.5; 6.1.4; 7.2}. **The supporting literature is provided in Chapter 7 Supplementary Material.**

Changes to the water cycle due to global warming is an essential driver of desertification and of the risks to livelihood, food production and vegetation in dryland regions. Changes in water scarcity due to climate change have already been detected in some dryland regions (section 7.2.2.4) and therefore the transition to moderate risk occurred in recent decades (*high confidence*). (IPCC 2018d) noted that in the case of risks to water resources, socio-economic drivers are expected to have a greater influence than the changes in climate (*medium confidence*). Indeed, in SSP1 there is only moderate risk even at 3°C of warming, due to the lower exposure and vulnerability of human population (Hanasaki et al. 2013a; Arnell and Lloyd-Hughes 2014; Byers et al. 2018b). Considering drylands only, (Byers et al. 2018b) estimate, using a time sampling approach for climate change and the 2050 population, that at 1.5°C, 2°C and 3°C, the dryland population exposed and vulnerable to water stress in SSP1 will be 2%, 3% and 3% respectively, thus indicating relatively stable moderate risks. In SSP3, the transition from moderate to high risk occurs in the range 1.2°C to 1.5 °C (*medium confidence*) and the transition from high to very high risk is in the range 1.5°C to 2.8 °C (*medium confidence*). (Hanasaki et al. 2013b) found a consistent increase in water stress at higher warming levels due in large part related to growth in population and demand for energy and agricultural commodities and to a lesser extent due to hydrological changes induced by global warming. In SSP3, (Byers et al. 2018b) estimate that at 1.5°C, 2°C and 3°C, the population exposed and vulnerable to water stress in drylands will steadily increase from 20% to 22% and 24%, respectively, thus indicating overall much higher risks compared to SSP1 for the same global warming levels.

SSP studies relevant to land degradation assess risks such as: number of people exposed to fire, the costs of floods and coastal flooding, and loss of ecosystem services including the ability of land to sequester carbon. The risks related to permafrost melting (section 7.2.2.7) are not considered here due to the lack of SSP studies addressing this topic. Climate change impacts on various components of land degradation have already been detected (sections 7.2.2.3; 7.2.2.5; 7.2.2.6) and therefore the transition from undetectable to moderate risk is in the range 0.7 °C –1°C (*high confidence*). Less than 100 million people are exposed to habitat degradation at 1.5°C under SSP1 in non-dryland regions, increasing to 257 million at 2°C (Byers et al. 2018). This suggests a gradual transition to high risk in the range 1.8°C to 2.8°C, but a *low confidence* is attributed due to the very limited evidence to constrain this transition.

1 By contrast in SSP3, there are already 107 million people exposed to habitat degradation at 1.5°C,
2 increasing to 1156 million people at 3°C (Byers et al. 2018b). Furthermore, (Knorr et al. 2016b)
3 estimate that 646 million people will be exposed to fire at 2°C warming, the main risk driver being the
4 high population growth in SSP3 rather than increased burned area due the climate change. Exposure
5 to extreme rainfall, a causative factor for soil erosion and flooding, also differs under SSPs. Under
6 SSP1 up to 14% of the land and population experience five day extreme precipitation events. Similar
7 levels of exposure occur at lower temperatures in SSP3 (Zhang et al. 2018b). Population exposed to
8 coastal flooding is lowest under SSP1 and higher under SSP3 with a limited effect of enhanced
9 protection in SSP3 already after 2°C warming (Hinkel et al. 2014). The transition from high to very
10 high risk will occur at 2.2°C –2.8°C in SSP3 (*medium confidence*), whereas this level of risk is not
11 expected to be reached in SSP1.
12

13 The greatest number of SSP studies explore climate change impacts relevant to food security,
14 including population at risk of hunger, food price increases, increases in disability adjusted life years
15 (Hasegawa et al. 2018a; Wiebe et al. 2015a; van Meijl et al. 2018a; Byers et al. 2018b). Changes in
16 crop yields and food supply stability have already been attributed to climate change (sections 7.2.2.1;
17 7.2.2.2) and the transition from undetectable to moderate risk is placed at 0.5°C – 1°C (*medium*
18 *confidence*). At 1.5°C, about 2 million people are exposed and vulnerable to crop yield change in
19 SSP1 (Hasegawa et al. 2018b; Byers et al. 2018b), implying moderate risk. A transition from
20 moderate to high risk is expected above 2.5°C (*medium confidence*) with population at risk of hunger
21 of the order of 100 million (Byers et al. 2018b). Under SSP3, high risks already exist at 1.5°C
22 (*medium confidence*), with 20 million people exposed and vulnerable to crop yield change. By 2°C,
23 178 million are vulnerable and 854 million people are vulnerable at 3°C (Byers et al. 2018b). This is
24 supported by the higher food prices increase of up to 20% in 2050 in a RCP6.0 scenario (i.e., slightly
25 below 2°C) in SSP3 compared to up to 5% in SSP1 (van Meijl et al. 2018). Furthermore in SSP3,
26 restricted trade increase this price effect (Wiebe et al. 2015). In SSP3, the transition from high to very
27 high risk is in the range 2°C –2.7°C (*medium confidence*) while this transition is never reached in
28 SSP1. This overall confirms that socio-economic development, by affecting exposure and
29 vulnerability, has an even larger effect than climate change for future trends in the population at risk
30 of hunger O'Neill et al. (2017) (p32). Changes can also threaten development gains (*medium*
31 *confidence*). Disability adjusted life years due to childhood underweight decline in both SSP1 and
32 SSP3 by 2030 (by 36.4 million disability adjusted life years in SSP1 and 16.2 million in SSP3).
33 However by 2050, disability adjusted life years increase by 43.7 million in SSP3 (Ishida et al. 2014).
34

35 7.2.3. Risks arising from responses to climate change

36 37 7.2.3.1. Risk associated with land-based adaptation

38 Land-based adaptation relates to a particular category of adaptation measures relying on land
39 management (Sanz et al. 2017). While most land-based adaptation options provide co-benefits for
40 climate mitigation and other land challenges (Chapter 6, 6.4.1), in some contexts adaptation measures
41 can have adverse side-effects, thus implying a risk to socio-ecological systems.

42 One example of risk is the possible decrease in farmer income when applying adaptive cropland
43 management measures. For instance, conservation agriculture including the principle of no-till
44 farming contribute to soil erosion management (Chap 6, 6.2. Yet, no-till management can reduce crop
45 yields in some regions, and although this effect is minimised when no-till farming is complemented
46 by the other two principle of conservation agriculture, this could induce a risk to livelihood in
47 vulnerable smallholder farming systems (Pittelkow et al. 2015).

48 Another example is the use of irrigation against water scarcity and drought. During the long lasting
49 drought from 2007–2009 in California, US, farmers adapted by relying on groundwater withdrawal
50 and caused groundwater depletion at unsustainable levels (Christian-Smith et al. 2015). The long term
51 effects of irrigation from groundwater may cause groundwater depletion, land subsidence, aquifer
52 overdraft, and saltwater intrusion (Tularam and Krishna 2009). Therefore, it is expected to increase

1 the vulnerability of coastal aquifers to climate change due to groundwater usage (Ferguson and
2 Gleeson 2012). The long term irrigation practice from groundwater may cause severe combination of
3 potential side effects and consequently irreversible results.

4 7.2.3.2. Risk associated with land-based mitigation

5 While historically land use activities have been a net source of GHG emissions, in future decades the
6 land sector will not only need to reduce its emissions, but also to deliver negative emissions through
7 Carbon Dioxide Removal (CDR) to reach the objective of limiting global warming at 2°C or below
8 (Chapter 2 Section 2.5). Although land-based mitigation in itself is a risk-reduction strategy aiming at
9 abating climate change, it also entails risks to humans and ecosystems depending on the type of
10 measures and the scale of deployment. These risks fall broadly into two categories: risk of mitigation
11 failure - due to uncertainties about mitigation potential, potential for sink reversal and moral hazard -
12 and risks arising from adverse side-effects - due to increased competition for land and water
13 resources. This section focuses specifically on bioenergy and BECCS since it is one of the most
14 prominent land-based mitigation strategies in future mitigation scenarios (along with large-scale forest
15 expansion discussed in Cross-Chapter Box 1: Scenarios, in Chapter 1) and it is assessed in Chapter 6
16 as being, at large scales, the only response option with adverse side-effects across all dimensions
17 (adaptation, food security, land degradation and desertification; see 6.4.1).

18 *Risk of mitigation failure.* The mitigation potential from bioenergy and BECCS is highly uncertain
19 with estimates ranging from 0.4 to 11.3 GtCO₂e yr⁻¹ for the technical potential while consideration of
20 sustainability constraints suggest an upper end around 5 GtCO₂e yr⁻¹ (Chapter 2, section 2.6). In
21 comparison, IAM-based mitigation pathways compatible with limiting global warming at 1.5°C
22 project bioenergy and BECCS deployment exceeding this range (Chapter 2, Fig. 2.24). There is
23 *medium confidence* that IAMs currently do not reflect the lower end and exceed the upper end of
24 bioenergy and BECCS mitigation potential estimates (Anderson and Peters 2016; Krause et al. 2018;
25 IPCC 2018c), with implications for the risk associated with reliance on bioenergy and BECCS
26 deployment for climate mitigation.

27 In addition, land-based CDR strategies are subject to a risk of carbon sink reversal. This implies a
28 fundamental asymmetry between mitigation achieved through fossil fuel emissions reduction
29 compared to CDR. While carbon in fossil fuel reserves - in the case of avoided fossil fuel emissions -
30 is locked permanently (at least over time scale of several thousand years), carbon sequestered into the
31 terrestrial biosphere – to compensate fossil fuel emissions – is subject to various disturbances in
32 particular from climate change and associated extreme events (Fuss et al. 2018; Dooley and Kartha
33 2018). The probability of sink reversal therefore increases with climate change, implying that the
34 effectiveness of land-based mitigation depends on emission reductions in other sectors and can be
35 sensitive to temperature overshoot (*high confidence*). In the case of bioenergy associated with CCS
36 (BECCS), the issue of the long-term stability of the carbon storage is linked to technical and
37 geological constraints, independent of climate change but presenting risks due to limited knowledge
38 and experience (Chapter 6; Cross-Chapter Box 7: Bioenergy, in Chapter 6).

39 Another factor in the risk of mitigation failure, is the moral hazard associated with CDR technologies.
40 There is *medium evidence and medium agreement* that the promise of future CDR deployment,
41 bioenergy and BECCS in particular, can deter or delay ambitious emission reductions in other sectors
42 (Anderson and Peters 2016; Markusson et al. 2018a; Shue 2018a). The consequences are an increased
43 pressure on land with higher risk of mitigation failure and of temperature overshoot and a transfer of
44 the burden of mitigation and unabated climate change to future generations. Overall, there is therefore
45 *medium evidence and high agreement* that prioritising early decarbonisation with minimal reliance on
46 CDR decreases the risk of mitigation failure and increases intergenerational equity (Geden et al. 2019;
47 Larkin et al. 2018; Markusson et al. 2018b; Shue 2018b).

48 *Risk from adverse side-effects.* At large scales, bioenergy (with or without CCS) is expected to
49 increase competition for land, water resources and nutrients, thus exacerbating the risks of food
50 insecurity, loss of ecosystem services and water scarcity (Chapter 6; Cross-Chapter Box 7: Bioenergy
51 in Chapter 6). Figure 7.3 shows the risk level (from undetectable to very high, aggregating risks of
52 food insecurity, loss of ecosystem services and water scarcity) as a function of the global amount of

1 land (million km²) used for bioenergy, considering second generation bioenergy. Two illustrative
 2 future socio-economic pathways (SSP1 and SSP3; see section 7.2.2 for more details) are depicted, in
 3 SSP3 the competition for land is exacerbated compared to SSP1 due to higher food demand resulting
 4 from larger population growth and higher consumption of meat-based products. The literature used in
 5 this assessment is based on IAM and non-IAM-based studies examining the impact of bioenergy crop
 6 deployment on various indicators, including food security (food prices or population at risk of hunger
 7 with explicit consideration of exposure and vulnerability), SDGs, ecosystem losses, transgression of
 8 various planetary boundaries and water consumption (see supplementary material). Since most of the
 9 assessed literature is centered around 2050 prevailing demographic and economic conditions for this
 10 year are used for the risk estimate. An aggregated risk metric including risks of food insecurity, loss
 11 of ecosystem services and water scarcity is used because there is no unique relationship between
 12 bioenergy deployment and the risk outcome for a single system. For instance, bioenergy deployment
 13 can be implemented in such a way that food security is prioritised at the expense of natural
 14 ecosystems, while the same scale of bioenergy deployment implemented with ecosystem safeguards
 15 would lead to a fundamentally different outcome in terms of food security (Boysen et al. 2017a).
 16 Considered as a combined risk, however, the possibility of a negative outcome on either food security,
 17 ecosystems or both can be assessed with less ambiguity and independently of possible implementation
 18 choices.
 19

20
21

22 **Figure 7.3: Risks associated with bioenergy crop deployment as a land-based mitigation strategy under**
 23 **two SSPs (SSP1 and SSP3). The assessment is based on literature investigating the consequences of**
 24 **bioenergy expansion for food security, ecosystem loss and water scarcity. These risk indicators were**
 25 **aggregated as a single risk metric in the figure. In this context, very high risk indicates that important**
 26 **adverse consequences are expected for all these indicators (more than 100 million people at risk of**
 27 **hunger, major ecosystem losses and severe water scarcity issues). The climate scenario considered is a**
 28 **mitigation scenario consistent with limiting global warming at 2°C (RCP2.6), however some studies**
 29 **considering other scenarios (e.g., no climate change) were considered in the expert judgement as well as**
 30 **results from other SSPs (e.g., SSP2). The literature supporting the assessment is provided in Table SM7.3.**

31 In SSP1, there is *medium confidence* that 1 to 4 million km² can be dedicated to bioenergy production
 32 without significant risks to food security, ecosystem services and water scarcity. At these scales of
 33 deployment, bioenergy and BECCS could have co-benefits for instance by contributing to restoration
 34 of degraded land and soils (Cross-Chapter Box 7: Bioenergy and BECCS in Chapter 6). Although
 35 currently degraded soils (up to 20 million km²) represent a large amount of potentially available land
 36 (Boysen et al. 2017a), trade-offs would occur already at smaller scale due to fertiliser and water use
 37 (Hejazi et al. 2014; Humpenöder et al. 2017; Heck et al. 2018a; Boysen et al. 2017b). There is *low*
 38 *confidence* that the transition from moderate to high risk is in the range 6-8.7 million km². In SSP1,
 39 (Humpenöder et al. 2017) found no important impacts on sustainability indicators at a level of 6.7
 40 million km², while (Heck et al. 2018b) note that several planetary boundaries (biosphere integrity;
 41 land-system change; biogeochemical flows; freshwater use) would be exceeded above 8.7 million
 42 km². There is *very high confidence* that all the risk transitions occur at lower bioenergy levels in
 43 SSP3, implying higher risks associated with bioenergy deployment, due to the higher competition for
 44 land in this pathway. In SSP3, land-based mitigation is therefore strongly limited by sustainability
 45 constraints such that moderate risk occur already between 0.5 and 1.5 million km² (*medium*

1 *confidence*). There is *medium confidence* that a bioenergy footprint beyond 4 to 8 million km² would
2 entail very high risk with transgression of most planetary boundaries (Heck et al. 2018b), strong
3 decline in sustainability indicators (Humpenöder et al. 2017) and increase in the population at risk of
4 hunger well above 100 million (Fujimori et al. 2018a; Hasegawa et al. 2018b).

6 **7.2.4. Risks arising from Hazard, Exposure, and Vulnerability**

7 Table 7.1 shows hazards from land-climate-society interactions identified in previous chapters, or in
8 other IPCC reports (with supplementary hazards appearing in the Appendix); the regions that are
9 exposed or will be exposed to these hazards; components of the land-climate systems and societies
10 that are vulnerable to the hazard; the risk associated with these impacts and the available indicative
11 policy responses. The last column shows representative supporting literature.

12 Included are forest dieback, extreme events in multiple economic and agricultural regimes (also see
13 7.2.2.1, 7.2.2.2), disruption in flow regimes in river systems, climate change mitigation impacts (also
14 see 7.2.3.2), competition for land (plastic substitution by cellulose, charcoal production), land
15 degradation and desertification (also see 7.2.2.8), loss of carbon sinks, permafrost destabilisation (also
16 see 7.2.2.7), and stranded assets (also see 7.3.4). Other hazards such as from failure of carbon storage,
17 renewable energy impacts on land use, wild-fire in forest-urban transition context, extreme events
18 effects on cultural heritage and urban air pollution from surrounding land-use are covered in Table 7.1
19 extension in the appendix as well in 7.5.6.

3 **7.3. Consequences of climate – land change for human well-being and** 4 **sustainable development**

5 To further explore what is at stake for human systems, this section assesses literature about potential
6 consequences of climate and land change for human well-being and ecosystems upon which humans
7 depend. Risks described in 7.2 have significant social, spiritual, and economic ramifications for
8 societies across the world and this section explores potential implications of the risks outlined above
9 to food security, livelihood systems, migration, ecosystems, species, infectious disease, and
10 communities and infrastructure. Because food and livelihood systems are deeply tied to one another,
11 combinations of climate and land change could pose higher present risks to humans and ecosystems
12 than examination of individual elements alone might suggest.

13 **7.3.1. What is at stake for food security?**

14 This section examines risks to food security when access to food is jeopardised by yield shortfall and
15 instability related to climate stressors. Past assessments of climate change impacts have sometimes
16 assumed that when grain and food yields in one area of the world are lower than expected, world trade
17 can redistribute food adequately to ensure food security. There is *medium confidence* that severe and
18 spatially extensive climatic stressors pose *high risk* to stability of and access to food for large numbers
19 of people across the world.

20 The 2007–2008, and 2010–2011 droughts in several regions of the world resulted in crop yield
21 decline that in turn led some governments to protect their domestic grain supplies rather than
22 engaging in free trade to offset food shortfalls in other areas of the world. These responses cascaded
23 and strongly affected regional and global food prices. Simultaneous crop yield impacts combined with
24 trade impacts have proven to play a larger and more pervasive role in global food crises than
25 previously thought (Sternberg 2012, 2017; Bellemare 2015) (Chatzopoulos et al. 2019). There is *high*
26 *confidence* that regional climate extremes already have significant negative domestic and international
27 economic impacts (Chatzopoulos et al. 2019).

28 **7.3.2. Risks to where and how people live: Livelihood systems and migration**

29 There is *high confidence* that climate- and land change interact with social, economic, political, and
30 demographic factors that affect how well and where people live (Sudmeier-Rieux et al. 2017;
31 Government Office for Science 2011; Laczko and Pigué 2014; Bohra-Mishra and Massey 2011;
32 Raleigh et al. 2015; Warner and Afifi 2011; Hugo 2011; Warner et al. 2012). There is *high evidence*
33 *and high agreement* that people move to manage risks and seek opportunities for their safety and
34 livelihoods, recognising that people respond to climatic change and land-related factors in tandem
35 with other variables (Hendrix and Salehyan 2012; Lashley and Warner 2015; van der Geest and
36 Warner 2014; Roudier et al. 2014; Warner and Afifi 2014)(McLeman 2013; Kaenzig and Pigué 2014;
37 Internal Displacement Monitoring Center 2017; Warner 2018; Cohen and Bradley 2010; Thomas and
38 Benjamin 2017). People move towards areas offering safety and livelihoods such as in rapidly
39 growing settlements in coastal zones (Black et al. 2013; Challinor et al. 2017; Adger et al. 2013);
40 burgeoning urban areas also face changing exposure to combinations of storm surges and sea level
41 rise, coastal erosion and soil and water salinisation, and land subsidence (Geisler and Currens 2017;
42 Maldonado et al. 2014; Bronen and Chapin 2013).

43 There is *medium confidence* that livelihood-related migration can accelerate in the short to medium
44 term when weather dependent livelihood systems deteriorate in relation to changes in precipitation,
45 changes in ecosystems, and land degradation and desertification (Abid et al. 2016)(Scheffran et al.
46 2012; Fussell et al. 2014; Bettini and Gioli 2016; Reyer et al. 2017)(Warner and Afifi 2014)(Handmer
47 et al. 2012; Nawrotzki and Bakhtsiyarava 2017; Nawrotzki et al. 2016; Steffen et al. 2015; Black et al.

1 2013). Slow onset climate impacts and risks can exacerbate or otherwise interact with social conflict
2 corresponding with movement at larger scales (see Section 7.2.3.2) and long term deterioration in
3 habitability of regions could trigger spatial population shifts (Denton et al. 2014).

4 There is *medium evidence* and *medium agreement* that climatic stressors can worsen the complex
5 negative impacts of strife and conflict (Schleussner et al. 2016; Barnett and Palutikof 2014; Scheffran
6 et al. 2012). Climate change and human mobility could be a factor that heightens tensions over scarce
7 strategic resources, a further destabilising influence in fragile states experiencing socio-economic and
8 political unrest (Carleton and Hsiang 2016a). Conflict and changes in weather patterns can worsen
9 conditions for people working in rain fed agriculture or subsistence farming, interrupting production
10 systems, degrading land and vegetation further (Papaioannou 2016; Adano and Daudi 2012). In recent
11 decades, droughts and other climatic stressors have compounded livelihood pressures in areas already
12 torn by strife (Tessler et al. 2015; Raleigh et al. 2015), such as in the Horn of Africa. Seizing of
13 agricultural land by competing factions, preventing food distribution in times of shortage have in this
14 region and others contributed to a triad of food insecurity, humanitarian need, and large movements of
15 people (Theisen et al. 2011; Mohammed et al. 2018; Ayeb-Karlsson et al. 2016; von Uexkull et al.
16 2016; Gleick 2014; Maystadt and Ecker 2014). People fleeing complex situations may return if
17 peaceful conditions can be established. Climate change and climate change induced development
18 responses in countries and regions are likely to exacerbate tensions over water and land its impact on
19 agriculture, fisheries, livestock and drinking water downstream. Shared pastoral landscapes used by
20 disadvantaged or otherwise vulnerable communities are particularly impacted by conflicts that are
21 likely to become more severe under future climate change (Salehyan and Hendrix 2014; Hendrix and
22 Salehyan 2012). Extreme events could considerably enhance these risks, in particular long-term
23 drying trends (Kelley et al. 2015; Cutter et al. 2012a). There is *medium evidence* and *medium*
24 *agreement* that governance is key in magnifying or moderating climate change impact and conflict
25 (Bonatti et al. 2016).

26 There is *low evidence and medium agreement* that longer-term deterioration in the habitability of
27 regions could trigger spatial population shifts (Seto 2011). Heat waves, rising sea levels that salinise
28 and inundate coastal and low-lying aquifers and soils, desertification, loss of geologic sources of
29 water such as glaciers and freshwater aquifers could affect many regions of the world and put life-
30 sustaining ecosystems under pressure to support human populations (Flahaux and De Haas 2016;
31 Chambwera et al. 2015; Tierney et al. 2015; Lilleør and Van den Broeck 2011).

32 **7.3.3. Risks to humans from disrupted ecosystems and species**

33 **Risks of loss of biodiversity and ecosystem services**

34 Climate change poses significant threat to species survival, and to maintaining biodiversity and
35 ecosystem services. Climate change reduces the functionality, stability, and adaptability of
36 ecosystems (Pecl et al. 2017). For example, drought affects cropland and forest productivity and
37 reduces associated harvests (provisioning services). In addition, extreme changes in precipitation
38 may reduce the capacity of forests to provide stability for groundwater (regulation and maintenance
39 services). Prolonged periods of high temperature may cause widespread death of trees in tropical
40 mountains, boreal and tundra forests, impacting diverse ecosystem services including impacting
41 aesthetic and cultural services (Verbyla 2011; Chapin et al. 2010; Krishnaswamy et al. 2014).
42 According to the Millennium Ecosystem Assessment (Millennium Ecosystem Assessment 2005),
43 climate change is likely to become one of the most significant drivers of biodiversity loss by the end
44 of the century.

45 There is *high confidence* that climate change already poses a moderate risk to biodiversity, and is
46 projected to become a progressively widespread and high risk in the coming decades; loss of Arctic
47 sea ice threatens biodiversity across an entire biome and beyond; the related pressure of ocean
48 acidification, resulting from higher concentrations of carbon dioxide in the atmosphere, is also already
49 being observed (UNEP 2009). There is ample evidence that climate change and land change
50 negatively affects biodiversity across wide spatial scales. Although there is relatively *limited evidence*
51 of current extinctions caused by climate change, studies suggest that climate change could surpass
52 habitat destruction as the greatest global threat to biodiversity over the next several decades (Pereira et

1 al. 2010). However, the multiplicity of approaches and the resulting variability in projections make it
2 difficult to get a clear picture of the future of biodiversity under different scenarios of global climatic
3 change (Pereira et al. 2010) . Biodiversity is also severely impacted by climate change induced land
4 degradation and ecosystem transformation (Pecl et al. 2017). This may impact humans directly and
5 indirectly through cascading impacts on ecosystem function and ecosystem services (Millennium
6 Assessment 2005). Climate change related human migration is likely to impact biodiversity as people
7 move into and contribute to land stress in biodiversity hotspots now and in the future; and as humans
8 concurrently move into areas where biodiversity is also migrating to adapt to climate change
9 (Oglethorpe et al. 2007).

10 **Climate and land change increases risk to respiratory and infectious disease**

11 In addition to risks related to nutrition articulated in Figure 7.1, human health can be affected by
12 climate change through extreme heat and cold, changes in infectious diseases, extreme events, and
13 land cover and land use (Hasegawa et al. 2016; Ryan et al. 2015; Terrazas et al. 2015; Kweka et al.
14 2016; Yamana et al. 2016). Evidence indicates that action to prevent the health impacts of climate
15 change could provide substantial economic benefits (Martinez et al. 2015; Watts et al. 2015).

16 Climate change exacerbates air pollution with increasing UV and ozone concentration. It has negative
17 impacts on human health and increases mortality rate especially in urban region (Silva et al. 2016,
18 2013; Lelieveld et al. 2013; Whitmee et al. 2015; Anenberg et al. 2010). In the Amazon, research
19 shows that deforestation (both net loss and fragmentation) will increase malaria, where vectors are
20 expected to increase their home range (Alimi et al. 2015; Ren et al. 2016), confounded with multiple
21 factors, such as social-economic conditions and immunity (Tucker Lima et al. 2017; Barros and
22 Honório 2015). Deforestation has been shown to enhance the survival and development of major
23 malaria vectors (Wang et al. 2016). The WHO estimates 60,091 additional deaths for climate change
24 induced malaria for the year 2030 and 32,695 for 2050 (World Health Organization 2014).

25 Human encroachment on animal habitat in combination with the bushmeat trade in Central African
26 countries has contributed to the increased incidence of zoonotic (i.e., animal-derived) diseases in
27 human populations, including Ebola virus epidemic (Alexander et al. 2015a; Nkengasong and
28 Onyebujoh 2018). The composition and density of zoonotic reservoir populations, such as rodents, is
29 also influenced by land-use and climate change (*high confidence*) (Young et al. 2017a). The bushmeat
30 trade in many regions of central and west African forests (particularly in relation to chimpanzee and
31 gorilla populations) elevates the risk of ebola by increasing human-animal contact (Harrod 2015).

32 **7.3.4. Risks to Communities and Infrastructure**

33 There is *high confidence* that policies and institutions which accentuate vicious cycles of poverty and
34 ill-health, land degradation and greenhouse gas emissions undermine stability and are barriers to
35 achieving climate resilient sustainable development. There is *high confidence* that change in climate
36 and land pose high periodic and sustained risk to the very young, those living in poverty, and ageing
37 populations. Older people are particularly exposed due to more restricted access to resources, changes
38 in physiology, and decreased mobility resulting from age which may limit adaptive capacity of
39 individuals and populations as a whole (Filiberto et al. 2010).

40 Combinations of food insecurity, livelihood loss related to degrading soils and ecosystem change, or
41 other factors that diminish the habitability of where people live disrupt social fabric and are currently
42 detected in most regions of the world (Carleton and Hsiang 2016b) There is *high confidence* that
43 coastal flooding and degradation already poses widespread and rising future risk to infrastructure
44 value and stranded infrastructure, as well as livelihoods made possible by urban infrastructure
45 (Radhakrishnan et al. 2017; Pathirana, A., Radhakrishnan, M., Quan 2018; Pathirana, A.,
46 Radhakrishnan, M., Ashley 2018; Radhakrishnan, M., Nguyen, H., Gersonius 2018; EEA 2016;
47 Pelling and Wisner 2012; Oke et al. 2017; Parnell and Walawege 2011; Uzun and Cete 2004; Melvin
48 et al. 2017).

49 There is *high evidence and high agreement* that climate and land change pose high risk to
50 communities and interdependent infrastructure systems including electric power, and transportation
51 are highly vulnerable and interdependent (Below et al. 2012; Adger et al. 2013; Pathirana, A.,

1 Radhakrishnan, M., Quan 2018)(Conway and Schipper 2011; Caney 2014; Chung Tiam Fook 2017;
2 Pathirana, A., Radhakrishnan, M., Quan 2018). These systems are exposed to disruption from severe
3 climate events such as weather-related power interruptions lasting for hours to days (Panteli and
4 Mancarella 2015). Increased magnitude and frequency of high winds, ice storms, hurricanes and heat
5 waves have caused widespread damage to power infrastructure and have caused severe outages,
6 affecting significant numbers of customers in urban and rural areas (Abi-Samra and Malcolm 2011).

7 Increasing populations, enhanced per capita water use, climate change, and allocations for water
8 conservation are potential threats to adequate water availability. As climate change produces
9 variations in rainfall, these challenges will intensify, evidenced by severe water shortages in recent
10 years in Capetown, Los Angeles, Rio de Janeiro among others (Watts et al. 2018; Majumder 2015;
11 Ashoori et al. 2015; Mini et al. 2015; Otto et al. 2015)(Cross-Chapter Box 5: Case study on policy
12 responses to drought in Chapter 3)(Ranatunga et al. 2014)(Ray and Shaw 2016; Gopakumar 2014).

14 **Cross-chapter Box 10: Economic dimensions of climate change** 15 **and land**

16 Koko Warner (The United States of America), Aziz Elbehri (Morocco), Marta Guadalupe Rivera
17 Ferre (Spain), Alisher Mirzabaev (Germany/Uzbekistan), Lindsay Stringer (United Kingdom), Anita
18 Wreford (New Zealand)

19
20 Sustainable land management (SLM) makes strong social and economic sense. Early action in
21 implementing SLM for climate change adaptation and mitigation provides distinct societal
22 advantages. Understanding the full scope of what is at stake from climate change presents challenges
23 because of inadequate accounting of the degree and scale at which climate change and land
24 interactions impact society, and the importance society places on those impacts (Santos et al.
25 2016)(7.2.2, 5.3.1, 5.3.2, 4.1). The consequences of inaction and delay bring significant risks
26 including irreversible change and loss in land ecosystem services, including food security, with
27 potentially substantial economic damage to many countries in many regions of the world (*high*
28 *confidence*).

29
30 This cross-chapter box brings together the salient economic concepts underpinning the assessments of
31 sustainable land management and mitigation options presented in this report. Four critical concepts
32 are required to help assess the social and economic implications of land-based climate action:

- 33 i. value to society;
- 34 ii. damages from climate and land-induced interventions on land ecosystems;
- 35 iii. costs of action and inaction;
- 36 iv. decision-making under uncertainty.

37 38 (i) **Value to society**

39 Healthy functioning land and ecosystems are essential for human health, food and livelihood security.
40 Land derives its value to humans from being both a finite resource and vital for life, providing vital
41 ecosystem services from water recycling, food, feed, fuel, biodiversity and carbon storage and
42 sequestration.

43
44 Many of these ecosystem services may be difficult to estimate in monetary terms, including when
45 they hold high symbolic value, linked to ancestral history, or traditional and indigenous knowledge
46 systems (Boillat and Berkes 2013). Such incommensurable values of land are core to social
47 cohesion—social norms and institutions, trust that enables all interactions, and sense of community.

48 49 (ii) **Damages from climate and land-induced interventions on land ecosystems;**

50 Values of many land-based ecosystem services and their potential loss under land-climate change
51 interaction can be considerable: the global value of ecosystem services was valued in 2011 at USD

1 125 trillion per year and the annual loss due to land use change was between USD 4.3 to 20.2 trillion
2 per year from 2007 (Costanza et al. 2014; Rockström et al. 2009). The annual costs of land
3 degradation are estimated to be about USD 231 billion per year or about 0.41% of the global GDP of
4 USD 56.49 trillion in 2007 (Nkonya et al. 2016) (4.4.1, 4.4.2).

5
6 Studies show increasingly negative effects on GDP from damage and loss to land-based values and
7 service as global mean temperatures increase, although the impact varies across regions (Kompas et
8 al. 2018).

9 10 **(iii) Costs of action and inaction**

11 Evidence suggests that the cost of inaction in mitigation and adaptation, and land use, exceeds the cost
12 of interventions in both individual countries, regions, and worldwide (Nkonya et al. 2016). Continued
13 inaction reduces the future policy option space, dampens economic growth and increases the
14 challenges of mitigation as well as adaptation (Moore and Diaz 2015)(Luderer et al. 2013). The cost
15 of reducing emissions is estimated to be considerably less than the costs of the damages at all levels
16 (Kainuma et al. 2013; Moran 2011; Sánchez and Maseda 2016).

17
18 The costs of adapting to climate impacts are also projected to be substantial, although evidence is
19 limited (summarised in Chambwera et al. 2014a). Estimates range from USD 9 to 166 billion per year
20 at various scales and types of adaptation, from capacity building to specific projects (Fankhauser
21 2017). Inadequate literature exists on the costs of adaptation in the agriculture or land-based sectors
22 (Wreford and Renwick 2012) due to lack of baselines, uncertainty around biological relationships and
23 inherent uncertainty about anticipated avoided damage estimates, but economic appraisal of actions to
24 maintain the functions of the natural environment and land sector generate positive net present values
25 (Adaptation Sub-committee 2013).

26
27 Preventing land degradation from occurring is considered more cost-effective in the long term
28 compared to the magnitude of resources required to restore already degraded land (Cowie et al.
29 2018a) (3.6.1). Evidence from drylands shows that each US dollar invested in land restoration
30 provides between 3 and 6 in social returns over a 30 year period, using a discount rate between 2.5
31 and 10% (Nkonya et al. 2016). SLM practices reverse or minimise economic losses of land
32 degradation, estimated at between USD 6.3 and 10.6 trillion annually, (ELD Initiative 2015) more
33 than five times the entire value of agriculture in the market economy (Costanza et al. 2014; Fischer et
34 al. 2017; Sandifer et al. 2015; Dasgupta et al. 2013) (3.7.5).

35
36 Across other areas such as food security, disaster mitigation and risk reduction, humanitarian
37 response, and healthy diet (malnutrition as well as disease), early action generates economic benefits
38 greater than costs (*high evidence, high agreement*) (Fankhauser 2017; Wilkinson et al. 2018; Venton
39 2018; Venton et al. 2012) (Clarvis et al. 2015)(Nugent et al. 2018) (Watts et al. 2018) (Bertram et al.
40 2018)(6.3, 6.4).

41 42 **(iv) Decision-making under uncertainty**

43 Given that significant uncertainty exists regarding the future impacts of climate change, effective
44 decisions must be made under unavoidable uncertainty (Jones et al., 2014).

45 Approaches that allow for decision-making under uncertainty are continually evolving (see 7.5). An
46 emerging trend is towards new frameworks that will enable multiple decision makers with multiple
47 objectives to explore the trade-offs between potentially conflicting preferences to identify strategies
48 that are robust to deep uncertainties (Singh et al. 2015; Driscoll et al. 2016; Araujo Enciso et al. 2016;
49 Herman et al. 2014; Pérez et al. 2016; Girard et al. 2015; Haasnoot et al. 2018; Roelich and Gieseckam
50 2019).

51 52 **Valuation of benefits and damages and costing interventions: Measurement issues**

53 Cost appraisal tools for climate adaptation are many and their suitability depends on the context
54 (7.5.2.2). Cost-benefit analysis (CBA) and cost-effectiveness analysis (CEA) are commonly applied,
55 especially for current climate variability situations. However, these tools are not without criticism and

1 their limitations have been observed in the literature (see Rogelj et al. 2018). In general measuring
2 costs and providing valuation are influenced by four conditions: measurement and valuation; the time
3 dimension; externalities; and aggregate versus marginal costs:

4
5 **Measurement and value issues**

6 Ecosystem services that are not traded in the market fall outside the formal or market-based valuation
7 and their value is thus either not accounted for or underestimated in both private and public decisions
8 (Atkinson et al. 2018). Environmental valuation literature uses a range of techniques to assign
9 monetary values to environmental outcomes where no market exists (Atkinson et al. 2018) (Dallimer
10 et al. 2018), but some values remain inestimable. For some indigenous cultures and peoples, land is
11 not considered something that can be sold and bought, so economic valuations are not meaningful
12 even as proxy approaches (Boillat and Berkes 2013)(Kumpula et al. 2011; Pert et al. 2015; Xu et al.
13 2005).

14
15 While a rigorous CBA is broader than a purely financial tool and can capture non-market values
16 where they exist, it can prioritise certain values over others (such as profit maximisation for owners,
17 efficiency from the perspective of supply chain processes, and judgements about which parties bear
18 the costs). Careful consideration of whose perspectives are considered when undertaking a CBA and
19 the limitations of these methods for policy interventions.

20
21 **Time dimension (short vs long term) and the issue of discount rates**

22
23 Economics uses a mechanism to convert future values to present day values known as discounting, or
24 the pure rate of time preference. Discount rates are increasingly being chosen to reflect concerns
25 about intergenerational equity, and some countries (e.g., the UK and France) apply a declining
26 discount rate for long term public projects. The choice of discount rate has important implications for
27 policy evaluation (Anthoff, Tol, & Yohe, 2010; Arrow et al., 2014; Baral, Keenan, Sharma, Stork, &
28 Kasel, 2014; Dasgupta et al., 2013; Lontzek, Cai, Judd, & Lenton, 2015; Sorokin et al., 2015; van den
29 Bergh & Botzen, 2014)(*high evidence, high agreement*). Stern (Stern 2007), for example, used a much
30 lower discount rate (giving almost equal weight to future generations) than the mainstream authors
31 (e.g., Nordhaus) and obtained much higher estimates of the damage of climate change.

32
33 **Positive and negative externalities (consequences and impacts not accounted for in
34 market economy),**

35 All land use generates externalities (unaccounted for side-effects of an activity). Examples include
36 loss of ecosystem services (e.g., reduced pollinators; soil erosion, increased water pollution,
37 nitrification etc.). Positive externalities include sequestration of CO₂ and improved soil water
38 filtration from afforestation. Externalities can also be social (e.g., displacement and migration) and
39 economic (e.g., loss of productive land). In the context of climate change and land, the major
40 externality is the AFOLU sourced emissions of GHGs. Examples of mechanisms to internalise
41 externalities are discussed in 7.5.

42
43 **Aggregate versus marginal costs**

44
45 Costs of climate change are often referred to through the marginal measure of the Social Cost of
46 Carbon (SCC), which measures the total net damages of an extra metric ton of CO₂ emissions due to
47 the associated climate change (Nordhaus 2014). The SCC can be used to determine a carbon price, but
48 SCC depends on discount rate assumptions and may neglect processes including large losses of
49 biodiversity, political instability, violent conflicts, large-scale migration flows, and the effects of
50 climate change on the development of economies (Stern 2013; Pezzey 2019).

51
52 At the sectoral level, marginal abatement cost (MAC) curves are widely used for the assessment of
53 costs related to CO₂ or GHG emissions reduction. MAC measures the cost of reducing one more GHG
54 unit and MAC curves are either expert-based or model-derived and offer a range of approaches and

1 assumptions on discount rates or available abatement technologies (Moran 2011).

3 **7.3.4.1. Windows of Opportunity**

4 Windows of opportunity are important learning moments wherein an event or disturbance in relation
5 to land, climate, and food security triggers responsive social, political, policy change (*medium*
6 *agreement*). Policies play an important role in windows of opportunity and are important in relation to
7 managing risks of desertification, soil degradation, food insecurity, and supporting response options
8 for sustainable land management (Chapter 6) (*high agreement*) (Kivimaa and Kern 2016; Gupta et al.
9 2013b; Cosens et al. 2017b; Darnhofer 2014; Duru et al. 2015).

10 A wide range of events or disturbances may initiate windows of opportunity ranging from climatic
11 events and disasters, recognition of a state of land degradation, an ecological social or political crisis,
12 and a triggered regulatory burden or opportunity. Recognition of a degraded system such as land
13 degradation and desertification (Chapters 3 and 4) and associated ecosystem feedbacks, allows for
14 strategies, response options and policies to address the degraded state (Nyström et al. 2012). Climate
15 related disasters (flood, droughts etc.) and crisis may trigger latent local adaptive capacities leading to
16 systemic equitable improvement (McSweeney and Coomes 2011), or novel and innovative
17 recombining of sources of experience and knowledge, allowing navigation to transformative social
18 ecological transitions (Folke et al. 2010). The occurrence of a series of punctuated crisis such as
19 floods or droughts, qualify as windows of opportunity when they enhance society's capacity to adapt
20 over the long term (Pahl-Wostl et al. 2013). A disturbance from an ecological, social, or political
21 crisis may be sufficient to trigger the emergence of new approaches to governance wherein there is a
22 change in the rules of the social world such as informal agreements surrounding human activities or
23 formal rules of public policies (Olsson et al. 2006; Biggs et al. 2017) (See 7.6). A combination of
24 socio-ecological changes may provide windows of opportunity for a socio-technical niche to be
25 adopted on a greater scale transforming practices towards sustainable land management such as
26 biodiversity based agriculture (Darnhofer 2014; Duru et al. 2015).

27 Policy may also create windows of opportunity. A disturbance may cause inconvenience, including
28 high costs of compliance with environmental regulations, thereby initiating a change of behaviour
29 (Cosens et al. 2017a). In a similar vein, multiple regulatory requirements existing at the time of a
30 disturbance may result in emergent processes and novel solutions in order to correct for piecemeal
31 regulatory compliance (Cosens et al. 2017a). Lastly, windows of opportunity can be created by policy
32 mixes or portfolio that provide for creative destruction of old social processes and thereby encourage
33 new innovative solutions (Kivimaa et al. 2017b) (See 7.4.8).

35 **7.4. Policy Instruments for Land and Climate**

36 This section outlines policy responses to risk. It describes multi-level policy instruments (7.4.1),
37 policy instruments for social protection (7.4.2), policies responding to hazard (7.4.3), GHG fluxes
38 (7.4.4), desertification (7.4.5), land degradation (7.4.6), economic instruments (7.4.7), enabling
39 effective policy instruments through policy mixes (7.4.8), and barriers to sustainable land
40 management and overcoming these barriers (7.4.9).

41 Policy instruments are used to influence behaviour and affect a response to do, not do, or continue to
42 do certain things (Anderson 2010) and can be invoked at multiple levels (international, national,
43 regional, and local) by multiple actors (See Table 7.2). For efficiency, equity and effectiveness
44 considerations, the appropriate choice of instrument for the context is critical, and across the topics
45 addressed in this report the instruments will vary considerably. A key consideration is whether the

1 benefits of the action will generate private or public social net benefits. Pannell (2008) provides a
2 widely-used framework for identifying the appropriate type of instrument depending on whether the
3 actions encouraged by the instrument are private or public, and positive or negative. Positive
4 incentives (such as financial or regulatory instruments) are appropriate where the public net benefits
5 are highly positive and the private net benefits are close to zero. This is likely to be the case for GHG
6 mitigation measures such as carbon pricing. Many other GHG mitigation measures (more effective
7 water or fertiliser use, better agricultural practices, less food waste, agroforestry systems, better forest
8 management) discussed in previous chapters may have substantial private as well as public benefit.
9 Extension (knowledge provision) is recommended for when public net benefits are highly positive and
10 private net benefits slightly positive, again for some GHG mitigation measures, and many adaptations,
11 food security and sustainable land management measures. Where the private net benefits are slightly
12 positive but the public net benefits highly negative, negative incentives (such as regulations and
13 prohibitions) are appropriate, for example over-application of fertiliser.

14 While Pannell (2008)'s framework is useful, it does not address considerations relating to the time-
15 scale of actions and their consequences particularly in the long time-horizons involved under climate
16 change: private benefits may accrue in the short term but become negative over time (Outka 2012)
17 and some of the changes necessary will require transformation of existing systems (Park et al. 2012;
18 Hadarits et al. 2017) for which a more comprehensive suite of instruments would be necessary.
19 Furthermore, the framework applies to private land ownership, so where land is in different ownership
20 structures, different mechanisms will be required. Indeed, land tenure is recognised as a factor in
21 barriers to Sustainable Land Management and an important Governance consideration (see 7.4.9,
22 7.6.4). A thorough analysis of the implications of policy instruments temporally, spatially and across
23 other sectors and goals (e.g., climate v. development) is essential before implementation to avoid
24 unintended consequences and achieve policy coherence (7.4.8).

25

26 **7.4.1. Multi-level Policy Instruments**

27 Policy responses and planning in relation to land and climate interactions occur at and across multiple
28 levels, involve multiple actors, and utilise multiple planning mechanisms (Urwin and Jordan 2008).
29 Climate change is occurring on a global scale while the impacts of climate change vary from region to
30 region and even within a region. Therefore, in addressing local climate impacts, local governments
31 and communities are key players. Advancing governance of *climate change* across all levels of
32 government and relevant stakeholders is crucial to avoid policy gaps between local action *plans* and
33 national/sub-national policy frameworks (Corfee-Morlot et al. 2009).

34 This section of the chapter identifies policies by level that respond to land and climate problems and
35 risks. As risk management in relation to land and climate occurs at multiple levels by multiple actors,
36 and across multiple sectors in relation to hazards (as listed on Table 7.2), risk governance, or the
37 consideration of the landscapes of risk arising from Chapters 2 through 6 is addressed in Sections 7.5
38 and 7.6. Categories of instruments include regulatory instruments (command and control measures),
39 economic and market instruments (creating a market, sending price signals, or employing a market
40 strategy), voluntary or persuasive instruments (persuading people to internalise behaviour), and
41 managerial (arrangements including multiple actors in cooperatively administering a resource or
42 overseeing an issue) (Gupta et al. 2013a; Hurlbert 2018b).

43 Given the complex spatial and temporal dynamics of risk, a comprehensive, portfolio of instruments
44 and responses is required to comprehensively manage risk. Operationalising a portfolio response can
45 mean layering, sequencing or integrating approaches. Layering means that within a geographical area,
46 households are able to benefit from multiple interventions simultaneously (e.g., those for family
47 planning and those for livelihoods development). A sequencing approach starts with those

1 interventions, which address the initial binding constraints, and then further interventions are later
2 added (e.g., the poorest households first receive grant-based support before then gaining access to
3 appropriate microfinance or market-oriented initiatives). Integrated approaches involve cross-sectoral
4 support within the framework of one program (Scott et al. 2016; Tengberg and Valencia 2018) (see
5 7.4.8, 7.5.6, and 7.6.3).

6 Climate related risk could be categorised by climate impacts such as flood, drought, cyclone etc.
7 (Christenson et al. 2014). Table 7.2 outlines instruments relating to impacts responding to the risk of
8 climate change, food insecurity, land degradation and desertification, and hazards (flood, drought,
9 forest fire), and GHG fluxes (climate mitigation).

1

Table 7.2 Policies/Instruments that address multiple land-climate risks at different jurisdictional levels

Scale	Policy/Instrument	Food Security	Land degradation & desertification	Sustainable land management	Climate related Extremes	GHG flux climate change mitigation
Global/ Cross Border	Finance mechanisms (also National)	X	X	X	X	X
	Certification (also National)		X	X		X
	Standards (including Risk Standards)(also National)		X	X	X	X
	Market based systems (also National)			X		X
	Payments for Ecosystem Services (also National)		X	X	X	X
	Disaster assistance (also National)					X
National	Taxes	X		X		X
	Subsidies	X	X	X		X
	Direct Income Payments (with Cross-Compliance)	X	X	X		X
	Border adjustments (e.g., tariffs)	X				X
	Grants	X	X	X	X	X
	Bonds	X	X	X		X
	Forecast-based finance, targeted microfinance	X	X	X		X
	Insurance (various forms)	X			X	
	Hazard information and communication (also sub-national and local)	X			X	
	Drought preparedness plans (also sub-national and local)	X			X	
	Fire policy (suppression or prescribed fire management)			X	X	X
	Regulations	X	X	X	X	X
	Land ownership laws (reform of, if necessary, for secure land title, or access/control)	X	X	X		
	Protected Area Designation and management		X	X		
	Extension – including skill and community development for livelihood diversification (also sub-national and local)	X	X	X	X	X
Sub-national	Spatial and landuse planning	X	X		X	
	Watershed management	X	X			
Local	Landuse zoning, spatial planning and integrated landuse planning	X		X	X	
	Community-based awareness programmes	X	X	X	X	X

2

This table highlights policy and instruments addressing key themes identified in this chapter;

3

an X indicates the relevance of the policy or instrument to the corresponding theme.

4

7.4.2. Policies for Food Security and Social Protection

There is *medium evidence* and *high agreement* that a combination of structural and non-structural policies is required in averting and minimising as well as responding to land and climate change risk, including food and livelihood security. If disruptions to elements of food security are long-lasting, policies are needed to change practices

If disruptions to food and livelihood systems are temporary, then policies aimed at stemming worsening human wellbeing and stabilising short-term income fluctuations in communities (such as increasing rural credit or providing social safety net programs) may be appropriate (Ward 2016).

7.4.2.1. Policies to ensure availability, access, utilisation, and stability of food

Food security is affected by interactions between climatic factors (rising temperatures, changes in weather variability and extremes), changes in land-use and land degradation, and socio-economic pathways and policy choices related to food systems (see Figure 7.1 and Figure 7.2). As outlined in Chapter 5, key aspects of food security are food availability, access to food, utilisation of food, and stability of food systems.

While comprehensive reviews of policy are rare and additional data is needed (Adu et al. 2018), evidence indicates the result of food security interventions vary widely due to differing values underlying the design of instruments. A large portfolio of measures is available to shape outcomes in these areas from the use of tariffs or subsidies to payments for production practices (OECD 2018). In the past, efforts to increase food production through significant investment in agricultural research including crop improvement have benefited farmers by increasing yields and reducing losses, and have helped consumers by lowering food prices (Pingali 2012, 2015; Alston and Pardey 2014; Popp et al. 2013). Public spending on agriculture research and development has been more effective at raising sustainable agriculture productivity than irrigation or fertiliser subsidies (OECD 2018). Yet, on average between 2015 and 2017, governments spent only around 14% of total agricultural support on services which includes physical and knowledge infrastructure, transport and ICT.

In terms of increasing food availability and supply, producer support, including policies mandating subsidies or payments, have been used to boost production of certain commodities or protect ecosystem services. Incentives can distort markets and farm business decisions in both negative and positive ways. For example, the European Union promotes meat and dairy production through voluntary coupled direct payments. These do not yet internalise external damage to climate, health, and groundwater (Velthof et al. 2014; Bryngelsson et al. 2016). In most countries, producer support has been declining since the mid-1990s (OECD 2018). Yet new evidence indicates that a government policy supporting producer subsidy could encourage farmers to adopt new technologies and reduce GHG reductions in agriculture (*medium evidence, high agreement*). However, this will require large capital (Henderson 2018). Since a 1995 reform in its Forest Law, Costa Rica has effectively used a combination of fuel tax, water tax, loans and agreements with companies, to pay landowners for agroforestry, reforestation and sustainable forest management (Porrás and Asquith 2018).

Inland capture fisheries and aquaculture are an integral part of nutrition security and livelihoods for large numbers of people globally (Welcomme et al. 2010; Hall et al. 2013; Tidwell and Allan 2001; Youn et al. 2014) and are increasingly vulnerable to climate change and competing land and water use (Allison et al. 2009; Youn et al. 2014). Future production may increase in some high-latitude regions (*low confidence*) but production is likely to decline in low latitude regions under future warming (*high confidence*) (Brander and Keith 2015; Brander 2007). However over-exploitation and degradation of rivers has resulted in a decreasing trend in contribution of capture fisheries to protein security in comparison to managed aquaculture (Welcomme et al. 2010). Aquaculture however competes for land and water resources with many negative ecological and environmental impacts (Verdegem and Bosma 2009; Tidwell and Allan 2001). Inland capture fisheries are undervalued in national and regional food security, ecosystem services and economy, are data deficient and are neglected in terms of supportive policies at national levels and absent in Sustainable Development Goals (Cooke et al. 2016; Hall et al. 2013; Lynch et al. 2016). Revival of sustainable capture fisheries and converting aquaculture to

1 environmentally less damaging management regimes is likely to succeed by investment in
2 recognition of their importance, improved valuation and assessment, secure tenure and adoption of
3 social, ecological and technological guidelines besides upstream-downstream river basin cooperation
4 and maintenance of ecological flow regimes in rivers (Youn et al. 2014; Mostert et al. 2007; Ziv et al.
5 2012; Hurlbert and Gupta 2016; Poff et al. 2003; Thomas 1996; FAO 2015a).

6 Extension services, and policies supporting agricultural extension systems, are also critical.
7 Smallholder farmer-dominated agriculture is currently the backbone of global food security in the
8 developing world. Without education and incentives to manage land and forest resources in a manner
9 that allows regeneration of both the soils and wood stocks, smallholder farmers tend to generate
10 income through inappropriate land management practices, engage in agricultural production on
11 unsuitable land and use fertile soils, timber and firewood for brick production and construction and
12 secondly engage in charcoal production (deforestation) as a coping mechanism (increasing income)
13 against food deficiency (Munthali and Murayama 2013). Through extension services, governments
14 can play a proactive role in providing information on climate and market risks, animal and plant
15 health. Farmers with greater access to extension training retain more crop residues for mulch on their
16 fields (Jaleta et al. 2015, 2013; Baudron et al. 2014).

17 Food security cannot be achieved by increasing food availability alone. Policy instruments, which
18 increase access to food at the household level, include safety net programming and universal basic
19 income. The graduation approach, developed and tested over the past decade using randomised
20 control trials in six countries, has lasting positive impacts on income, as well as food and nutrition
21 security (Banerjee et al. 2015; Raza and Poel 2016) (*robust evidence, high agreement*). The
22 graduation approach layers and integrates a series of interventions designed to help the poorest:
23 consumption support in the form of cash or food assistance, transfer of an income generating asset
24 (such as a livestock) and training on how to maintain the asset, assistance with savings and coaching
25 or mentoring over a period of time to reinforce learning and provide support. Due to its success, the
26 graduation approach is now being scaled up, now used in over 38 countries and included by an
27 increasing number of governments in social safety-net programs (Hashemi, S.M. and de Montesquiou
28 2011).

29 At the national and global level, food price and trade policies impact access to food. Fiscal policies,
30 such as taxation, subsidies, or tariffs, can be used to regulate production and consumption of certain
31 foods and can affect environmental outcomes. In Denmark, tax on saturated fat content of food
32 adopted to encourage healthy eating habits accounted for 0.14% of total tax revenues between 2011
33 and 2012 (Sassi et al. 2018). A global tax on GHG emissions for example has large mitigation
34 potential and will generate tax revenues, but may also result in large reductions in agricultural
35 production (Henderson 2018). Consumer-level taxes on GHG intensive food may be applied to
36 address competitiveness issues between different countries, if some countries use taxes while others
37 do not. However, increases in prices might impose disproportionate financial burdens on low-income
38 households, and may not be publicly acceptable. A study examining the relationship between food
39 prices and social unrest found that between 1990 and 2011, food price increases have led to increases
40 in social unrest, whereas food price volatility has not been associated with increases in social unrest
41 (Bellemare 2015).

42 Interventions that allow people to maximise their productive potential while protecting the ecosystem
43 services may not ensure food security in all contexts. Some household land holdings are so small that
44 self-sufficiency is not possible (Venton 2018). Value chain development has in the past increased
45 farm income but delivered fewer benefits to vulnerable consumers (Bodnár et al. 2011). Ultimately, a
46 mix of production activities and consumption support is needed. Consumption support can be used to
47 help achieve the second important element of food security – access to food.

48 Agricultural technology transfer can help optimise food and nutrition security (see 7.4.4.3). Policies
49 that affect agricultural innovation span sectors and include “macro-economic policy-settings;
50 institutional governance; environmental standards; investment, land, labor and education policies; and
51 incentives for investment, such as a predictable regulatory environment and robust intellectual
52 property rights”.

1 The scientific community can partner across sectors and industries for better data sharing, integration,
2 and improved modelling and analytical capacities (Janetos et al. 2017; Lunt et al. 2016). To better
3 predict, respond to and prepare for concurrent agricultural failures, and gain a more systematic
4 assessment of exposure to agricultural climate risk, large data gaps need to be filled, as well as gaps in
5 empirical foundation and analytical capabilities (Janetos et al. 2017; Lunt et al. 2016). Data required
6 include global historical datasets, many of which are unreliable, inaccessible, or not available
7 (Maynard 2015; Lunt et al. 2016). Participation in co-design for scenario planning can build social
8 and human capital while improving understanding of food system risks and creating innovative ways
9 for collectively planning for a more equitable and resilient food system (Himanen et al. 2016; Meijer
10 et al. 2015; Van Rijn et al. 2012).

11 Demand management for food, including promoting healthy diets, reducing food loss and waste, is
12 covered in Chapter 5. There is a gap in knowledge regarding what policies and instruments support
13 demand management. There is *robust evidence and robust agreement* that changes in household
14 wealth and parents' education can drive changes in diet and improvements in nutrition (Headey et al.
15 2017). Bangladesh has managed to sustain a rapid reduction in the rate of child undernutrition for at
16 least two decades. Rapid wealth accumulation and large gains in parental education are the two largest
17 drivers of change (Headey et al. 2017). Educating consumers, and providing affordable alternatives,
18 will be critical to changing unsustainable food use habits relevant to climate change.

19 **7.4.2.2. Policies to secure social protection**

20 There is *medium evidence and high agreement* from all regions of the world that safety nets and social
21 protection schemes can provide stability which prevents and reduces abject poverty (Barrientos 2011;
22 Hossain 2018) (Cook and Pincus 2015; Huang and Yang 2017; Slater 2011; Sparrow et al. 2013;
23 Rodriguez-Takeuchi and Imai 2013; Bamberg et al. 2018) in the face of climatic stressors and land
24 change (Davies et al. 2013; Cutter et al. 2012b; Pelling 2011; Ensor 2011).

25 The World Bank estimates that globally social safety net transfers have reduced the absolute poverty
26 gap by 45% and the relative poverty gap by 16% (World Bank 2018). Adaptive social protection
27 builds household capacity to deal with shocks as well as the capacity of social safety nets to respond
28 to shocks. For low-income communities reliant on land and climate for their livelihoods and
29 wellbeing, social protection provides a way for vulnerable groups to manage weather and climatic
30 variability and deteriorating land conditions to household income and assets (*robust evidence, high
31 agreement*)(Baulch et al. 2006; Barrientos 2011; Harris 2013; Fiszbein et al. 2014; Kiendrebeogo et
32 al. 2017; Kabeer et al. 2010; FAO 2015b; Warner et al. 2018)(World Bank 2018).

33 Life cycle approaches to social protection are one approach, which some countries (such as
34 Bangladesh) are using when developing national social protection policies. These policies
35 acknowledge that households face risks across the life cycle from which they need to be protected. If
36 shocks are persistent, or occur numerous times, then policies can address concerns of a more
37 structural nature (Glauben et al. 2012). Barrett (2005), for example, distinguishes between the role of
38 safety nets (which include programs such as emergency feeding programs, crop or unemployment
39 insurance, disaster assistance, etc.) and cargo nets (which include land reforms, targeted microfinance,
40 targeted school feeding program, etc.). While the former prevents non-poor and transient poor from
41 becoming chronically poor, the latter is meant to lift people out of poverty by changing societal or
42 institutional structures. The graduation approach has adopted such systematic thinking with successful
43 results (Banerjee et al. 2015).

44 Social protection systems can provide buffers against shocks through vertical or horizontal expansion,
45 piggybacking on pre-established programmes, aligning social protection and humanitarian systems or
46 refocusing existing resources (Wilkinson et al. 2018; O'Brien, C.O., Scott, Z., Smith, G., Barca, V.,
47 Kardan, A., Holmes, R. Watson 2018); (Jones and Presler-Marshall 2015). There is increasing
48 evidence that forecast-based financing, linked to a social protection, can be used to enable
49 anticipatory actions based on forecast triggers and guaranteed funding ahead of a shock (Jjemba et al.
50 2018). Accordingly scaling up social protection based on an early warning could enhance timeliness,
51 predictability and adequacy of social protection benefits (Kuriakose et al. 2012; Costella et al. 2017a;

1 Wilkinson et al. 2018; O'Brien, C.O., Scott, Z., Smith, G., Barca, V., Kardan, A., Holmes, R. Watson
2 2018).

3 Countries at high-risk of natural disasters often have lower safety net coverage percent (World Bank
4 2018), and there is *medium evidence and medium agreement* that those countries with few financial
5 and other buffers have lower economic and social performance (Cutter et al. 2012b; Outreville
6 2011a). Social protection systems have also been seen as an unaffordable commitment of public
7 budget in many developing and low-income countries (Harris 2013). National systems may be
8 disjointed and piecemeal, and subject to cultural acceptance and competing political ideologies (Niño-
9 Zarazúa et al. 2012). For example, Liberia and Madagascar each have five different public works
10 programs, each with different donor organisations and different implementing agencies (Monchuk
11 2014). These implementation shortcomings mean that positive effects of social protection systems
12 might not be robust enough to shield recipients completely against the impacts of severe shocks or
13 from long-term losses and damages from climate change (*limited evidence, high agreement*) (Davies et
14 al. 2009; Umukoro 2013; Béné et al. 2012; Ellis et al. 2009).

15 There is increasing support for establishment of public-private safety nets to address climate related
16 shocks which are augmented by proactive preventative (adaptation) measures and related risk transfer
17 instruments that are affordable to the poor (Kousky et al. 2018b). Studies suggest that adaptive
18 capacity of communities have improved with regard to climate variability like drought when ex-ante
19 tools including insurance have been employed holistically; providing insurance in combination with
20 early warning and institutional and policy approaches that aim to reduce livelihood and food
21 insecurity as well as strengthen social structures (Shiferaw et al. 2014; Lotze-Campen and Popp 2012).
22 Bundling insurance with early warning and seasonal forecasting can reduce the cost of insurance
23 premiums (Daron and Stainforth 2014). The regional risk insurance scheme Africa Risk Capacity has
24 the potential to significantly reduce the cost of insurance premiums (Siebert 2016) while bolstering
25 contingency planning against food insecurity.

26 Work-for-insurance programs applied in the context of social protection have been shown to improve
27 livelihood and food security in Ethiopia (Berhane 2014; Mohammed et al. 2018) and Pakistan . The R4
28 Rural Resilience Program in Ethiopia is a widely cited example of a program that serves the most
29 vulnerable and includes aspects of resource management, and access by the poor to financial services
30 including insurance and savings (Linnerooth-bayer et al. 2018). Weather index insurance (such as
31 index based crop insurance) is being presented to low-income farmers and pastoralists in developing
32 countries (e.g., Ethiopia, India, Kazakhstan, China, South Asia) to complement informal risk sharing,
33 reducing the risk of lost revenue associated with variations in crop yield, and provide an alternative to
34 classic insurance (Bogale 2015a; Conradt et al. 2015; Dercon et al. 2014; Greatrex et al. 2015;
35 McIntosh et al. 2013). The ability of insurance to contribute to adaptive capacity depends on the
36 overall risk management and livelihood context of households — studies find that rain fed
37 agriculturalists and foresters with more years of education and credit but limited off-farm income are
38 more willing to pay for insurance than households who have access to remittances (such as from
39 family members who have migrated) (Bogale 2015a; Gan et al. 2014; Hewitt et al. 2017; Nischalke
40 2015). In Europe, modelling suggests that insurance incentives such as vouchers would be less
41 expensive than total incentivised damage reduction and may reduce residential flood risk by 12% in
42 Germany and 24% by 2040 (Hudson et al. 2016).

43 **7.4.3. Policies Responding to Climate Related Extremes**

44 **7.4.3.1. Risk Management Instruments**

45 Risk management addressing climate change has broadened to include mitigation, adaptation and
46 disaster preparedness in a process of risk management through instruments facilitating contingency
47 and cross sectoral planning (Hurlimann and March 2012; Oels 2013), social community planning, and
48 strategic, long term planning (Serrao-Neumann et al. 2015a). A comprehensive consideration
49 integrates principles from informal support mechanisms to enhance formal social protection
50 programming (Mobarak and Rosenzweig 2013; Stavropoulou et al. 2017) such that the social safety
51 net, disaster risk management, and climate change adaptation are all considered to enhance
52

1 livelihoods of the chronic poor (see char dwellers and recurrent floods in Jamuna and Brahmaputra
2 basins of Bangladesh (Awal 2013) (see also 7.4.7). Iterative risk management is an on-going process
3 of assessment, action, reassessment and response (Mochizuki et al. 2015) (see 7.5.2 and 7.4.7.2).

4 Important elements of risk planning include education, creation of hazard and risk maps; important
5 elements of predicting include hydrological and meteorological monitoring to forecast weather,
6 seasonal climate forecasts, aridity, flood and extreme weather; effective responding requires robust
7 communication systems that pass on information to enable response (Cools et al. 2016).

8 Gauging effectiveness of policy instruments is challenging. Timescale may influence outcomes. To
9 evaluate effectiveness researchers, program managers and communities strive to develop consistency,
10 comparability, comprehensiveness and coherence in their tracking. In other words, practitioners utilise
11 a consistent and operational conceptualisation of adaptation; focus on comparable units of analysis;
12 develop comprehensive datasets on adaptation action; and be coherent with our understanding of what
13 constitutes real adaptation (Ford and Berrang-Ford 2016). Increasing the use of systematic reviews or
14 randomised evaluations may also be helpful (Alverson and Zommers 2018).

15 Many risk management policy instruments are referred to by the International Organization of
16 Standardization which lists risk management principles, guidelines, and frameworks for explaining
17 the elements of an effective risk management program (ISO 2009). The standard provides practical
18 risk management instruments and makes a business case for risk management investments (McClellan
19 et al. 2010). Insurance addresses impacts associated with extreme weather events (storms, floods,
20 droughts, temperature extremes), but it can provide disincentives for reducing disaster risk at the local
21 level through the transfer of risk spatially to other places or temporally to the future (Cutter et al.
22 2012b) and uptake is unequally distributed across regions and hazards (Lal et al. 2012). Insurance
23 instruments (see 7.4.2 and 7.4.6) can take many forms (traditional indemnity based, market based crop
24 insurance, property insurance), and some are linked to livelihoods sensitive to weather as well as food
25 security (linked to social safety net programs) and ecosystems (coral reefs and mangroves). Insurance
26 instruments can also provide a framework for risk signals to adaptation planning and implementation
27 and facilitate financial buffering when climate impacts exceed current capabilities delivered through
28 both public and private finance (Bogale 2015b; Greatrex et al. 2015; Surminski et al. 2016). A
29 holistic consideration of all instruments responding to extreme impacts of climate change (drought,
30 flood etc.) is required when assessing if policy instruments are promoting livelihood capitals and
31 contributing to the resilience of people and communities (Hurlbert 2018b). This holistic consideration
32 of policy instruments leads to a consideration of risk governance (see 7.6).

33 Early warning systems are critical policy instruments for protecting lives and property, adapting to
34 climate change, and effecting adaptive climate risk management (*high confidence*) (Selvaraju 2011;
35 Cools et al. 2016; Travis 2013; Henriksen et al. 2018; Seng 2013; Kanta Kafle 2017; Garcia and
36 Fearnley 2012). Early warning systems exist at different levels and for different purposes including
37 the FAO global Information and Early Warning System (GIEWS) on food and agriculture, USAID
38 Famine, national and local extreme weather, species extinction, community based flood and landslide,
39 and informal pastoral drought early warning systems (Kanta Kafle 2017). Medium term warning
40 systems can identify areas of concern, hotspots of vulnerabilities and sensitivities, or critical zones of
41 land degradation (areas of concern)(see chapter 6) critical to reduce risks over five to ten years
42 (Selvaraju 2012). Early warning systems for dangerous climate shifts are emerging with
43 considerations of rate of onset, intensity, spatial distribution and predictability. Growing research in
44 the area is considering positive and negative lessons learned from existing hazard early warning
45 systems including lead time and warning response (Travis 2013).

46 For effectiveness, communication methods are best adapted to local circumstances, religious and
47 cultural based structures and norms, information technology, and local institutional capacity (Cools et
48 al. 2016; Seng 2013). Considerations of governance or the actors and architecture within the socio-

1 ecological system, is an important feature of successful early warning system development (Seng
2 2013). Effective early warning systems consider the critical links between hazard monitoring, risk
3 assessment, forecasting tools, warning and dissemination (Garcia and Fearnley 2012). These effective
4 systems incorporate local context by defining accountability, responsibility, acknowledging the
5 importance of risk perceptions and trust for an effective response to warnings. Although increasing
6 levels and standardisation nationally and globally is important, revising these systems through
7 participatory approaches cognizant of the tension with technocratic approaches improves success
8 (Cools et al. 2016; Henriksen et al. 2018; Garcia and Fearnley 2012).

9 **7.4.3.2. Drought related risk minimising instruments**

10 A more detailed review of drought instruments, and three broad policy approaches for responding to
11 drought, is provided in Cross-chapter Box 5: Case study on policy drought in Chapter 3. Three broad
12 approaches include: (1) early warning systems and response to the disaster of drought (through
13 instruments such as disaster assistance or crop insurance); (2) disaster response ex-ante preparation
14 (through drought preparedness plans); and (3) drought risk mitigation (proactive policies to improve
15 water use efficiency, make adjustments to water allocation, funds or loans to build technology such as
16 dugouts or improved soil management practices).

17 Drought plans are still predominantly reactive crisis management plans rather than proactive risk
18 management and reduction plans. Reactive crisis management plans treat only the symptoms and are
19 inefficient drought management practices. More efficient drought preparedness instruments are those
20 that address the underlying vulnerability associated with the impacts of drought thereby building
21 agricultural producer adaptive capacity and resilience (*high confidence*)(Cross-chapter Box 5: Case
22 study on policy drought, chapter 3).

23 **7.4.3.3. Fire related risk minimising instruments**

24 There is *robust evidence and high agreement* that fire strategies need to be tailored to site specific
25 conditions in an adaptive application that is assessed and reassessed over time (Dellasala et al. 2004;
26 Rocca et al. 2014). Strategies for fire management include fire suppression, prescribed fire and
27 mechanical treatments (such as thinning the canopy), and allowing wildfire with little or no active
28 management (Rocca et al. 2014). Fire suppression can degrade the effectiveness of forest fire
29 management in the long run (Collins et al. 2013).

30 Different forest types have different fire regimes and require different fire management policies
31 (Dellasala et al. 2004). For instance, Cerrado, a fire dependent savannah, utilises a fire management
32 policy different than the fire suppression policy (Durigan and Ratter 2016). The choice of strategy
33 depends on local considerations including land ownership patterns, dynamics of local meteorology,
34 budgets, logistics, federal and local policies, tolerance for risk and landscape contexts. In addition
35 there are trade-offs among the management alternatives and often no single management strategy will
36 simultaneously optimise ecosystem services including water quality and quantity, carbon
37 sequestration, or run off erosion prevention (Rocca et al. 2014).

38 **7.4.3.4. Flood related risk minimising instruments**

39 Flood risk management consists of command and control measures including spatial planning and
40 engineered flood defences (Filatova 2014), financial incentive instruments issued by regional or
41 national governments to facilitate cooperative approaches through local planning, enhancing
42 community understanding and political support for safe development patterns and building standards,
43 and regulations requiring local government participation and support for local flood planning (Burby
44 and May 2009). However, Filatova (2014) found that if autonomous adaptation is downplayed, people
45 are more likely to make land use choices that collectively lead to increased flood risks and leave costs
46 to governments. Taxes and subsidies that do not encourage (and even counter) perverse behaviour
47 (such as rebuilding in flood zones) are important instruments mitigating this cost to government.
48 Flood insurance has been found to be maladaptive as it encourages rebuilding in flood zones (O'Hare

1 et al. 2016)) and government flood disaster assistance negatively impacts average insurance coverage
2 the following year (Kousky et al. 2018a). Modifications to flood insurance can counter perverse
3 behaviour. One example is the provision of discounts on flood insurance for localities that undertake
4 one of 18 flood mitigation activities including structural mitigation (constructing dykes, dames, flood
5 control reservoirs), and non-structural initiatives such as point source control and watershed
6 management efforts, education and maintenance of flood-related databases (Zahran et al. 2010). Flood
7 insurance that provides incentives for flood mitigation, marketable permits and transferable
8 development rights (see case study of Flood and Food Security in Section 7.6) instruments can
9 provide price signals to stimulate autonomous adaptation, countering barriers of path dependency, and
10 the time lag between private investment decisions and consequences (Filatova 2014). To build
11 adaptive capacity, consideration needs to be made of policy instruments responding to flood including
12 flood zone mapping, land use planning, flood zone building restrictions, business and crop insurance,
13 disaster assistance payments, preventative instruments including environmental farm planning
14 (including soil and water management (see Chapter 6)) and farm infrastructure projects, and recovery
15 from debilitating flood losses ultimately through bankruptcy (Hurlbert 2018a). Non-structural
16 measures have been found to advance sustainable development as they are more reversible,
17 commonly acceptable and environmentally friendly (Kundzewicz 2002).

19 **7.4.4. Policies Responding to GHG fluxes**

20 **7.4.4.1. GHG fluxes and climate change mitigation**

21 Pathways reflecting current nationally stated mitigation ambitions as submitted under the Paris
22 Agreement would not limit global warming to 1.5°C with no or limited overshoot, but instead result
23 in a global warming of about 3°C by 2100 with warming continuing afterwards (IPCC 2018d).
24 Reversing warming after an overshoot of .2°C or larger during this century would require deployment
25 of CDR at rates and volumes that might not be achievable given considerable implementation
26 challenges (IPCC 2018d). This significant gap (Höhne et al. 2017; Rogelj et al. 2016) creates a
27 significant risk of global warming impacting land degradation, desertification, and food security (see
28 7.2;(IPCC 2018d). Action can be taken by 2030 adopting already known cost effective technology
29 (United Nations Environment Programme 2017), improving the finance, capacity building, and
30 technology transfer mechanisms of the UNFCCC, improving food security (listed by 73 nations in
31 their NDCs) and nutritional security (listed by 25 nations) (Richards, M., Bruun, T.B., Campbell,
32 B.M., Gregersen, L.E., Huyer 2015). UNFCCC Decision 1.CP21 reaffirmed the UNFCCC target that
33 ‘developed country parties provide USD 100 billion annually by 2020 for climate action in
34 developing countries’ (Rajamani 2011) and a new collective quantified goal above this floor is to be
35 set taking into account the needs and priorities of developing countries (Fridahl and Linnér 2016).

36 Mitigation policy instruments to address this shortfall include financing mechanisms, carbon pricing,
37 cap and trade or emissions trading, and technology transfer. While climate change is a global
38 commons problem containing free-riding problems, cost effective international policies that insure
39 countries get the most environmental benefit out of mitigation investments promote an international
40 climate policy regime (Nordhaus 1999; Aldy and Stavins 2012). Carbon pricing instruments may
41 provide an entry point for inclusion of agricultural appropriate carbon instruments. Models of cost
42 efficient distribution of mitigation across regions and sectors typically employ a global uniform
43 carbon price, but such treatment in the agricultural sector may impact food security (see 7.4.4.4).

44 One policy initiative to advance climate mitigation policy coherence (see 7.4.8) in this section is the
45 phase out of subsidies for fossil fuel production. The G20 agreed in 2009, and the G7 agreed in 2016,
46 to phase out these subsidies by 2025. Subsidies include lower tax rates or exemptions and rebates of

1 taxes on fuels used by particular consumers (diesel fuel used by farming, fishing etc.), types of fuel, or
2 how fuels are used. The OECD estimates the overall value of these subsidies to be between USD 160–
3 200 billion annually between 2010 and 2014 (OECD 2015). The phase out of fossil fuel subsidies has
4 important economic, environmental and social benefits. Coady et al. (2017) estimate the economic
5 and environmental benefits of reforming fossil fuel subsidies could be valued worldwide at USD 4.9
6 trillion in 2013, and USD 5.3 trillion in 2015. Eliminating subsidies could have reduced emissions by
7 21% and raised 4% of global GDP as revenue (in 2013) and improved social welfare (Coady et al.
8 2017).

9 Legal instruments addressing perceived deficiencies in climate change mitigation include human
10 rights and liability. Developments in attribution science are improving the ability to detect human
11 influence on extreme weather and Marjanac et al. (2017) argue this broadens the legal duty of
12 government, business and others to manage foreseeable harms and may lead to more climate change
13 litigation (Marjanac et al. 2017). Peel and Osofsky (2017) argue that courts are becoming increasingly
14 receptive to employ human rights claims in climate change lawsuits (Peel and Osofsky 2017); citizen
15 suits in domestic courts are not a universal phenomenon and even if unsuccessful, Estrin (2016)
16 concludes they are important in underlining the high level of public concern.

17 **7.4.4.2. Mitigation instruments**

18 Similar instruments for mitigation could be applied to the land sector as in other sectors, including
19 market-based measures such as taxes and cap and trade systems; as well as standards and regulations;
20 subsidies and tax credits; information instruments and management tools; R&D investment; and
21 voluntary compliance programmes, but few regions have implemented agricultural mitigation
22 instruments (Cooper et al. 2013). Existing regimes focus on subsidies, grants and incentives, and
23 voluntary offset programmes.

24 **Market-based instruments**

25 Although carbon pricing is recognised to be an important cost-effective instrument in a portfolio of
26 climate policies (Aldy et al. 2010) (*high evidence, high agreement*), as yet no country is exposing
27 their agricultural sector emissions to carbon pricing in any comprehensive way. A carbon tax, fuel
28 tax, and carbon markets (cap and trade system or Emissions Trading Scheme (ETS), or baseline and
29 credit schemes, and voluntary markets) are predominant policy instruments that implement carbon
30 pricing. The advantage of carbon pricing is environmental effectiveness at relatively low cost
31 (Baranzini et al. 2017; Fawcett et al. 2014) (*high evidence, high agreement*). Furthermore, carbon
32 pricing could be used to raise revenue to reinvest in public spending, either to help certain sectors
33 transition to lower carbon systems, or to invest in public spending unrelated to climate change. Both
34 of these options may make climate policies more attractive and enhance overall welfare (Siegmeier et
35 al. 2018), but there is as yet no evidence of the effectiveness of emissions pricing in agriculture
36 (Grosjean et al. 2018). There is however, a clear need for progress in this area as without effective
37 carbon pricing, the mitigation potential identified in chapters 5 and 6 of this report will not be realised
38 (Boyce 2018) (*high evidence, high agreement*).

39 The price may be set at the Social Cost of Carbon (the incremental impact of emitting an additional
40 tonne of CO₂, or the benefit of slightly reducing emissions), but estimates of the SCC vary widely and
41 are contested (Pezzey 2019) (*high evidence, high agreement*). An alternative to the SCC includes a
42 pathways approaches that sets an emissions target and estimates the Carbon prices required to achieve
43 this at the lowest possible cost (Pezzey 2019). Theoretically, higher costs throughout the entire
44 economy result in reduction of carbon intensity as consumers and producers adjust their decisions in
45 relation to prices corrected to reflect the climate externality (Baranzini et al. 2017).

46 Both carbon taxes and cap and trade systems can reduce emissions, but cap and trade systems are
47 generally more cost effective (*medium evidence, high agreement*) (Haites 2018a). In both cases, the

1 design of the system is critical to its effectiveness at reducing emissions (Bruvoll and Larsen 2004;
2 (Lin and Li 2011)) (*high evidence, high agreement*). The trading system allows the achievement of
3 emission reductions in the most cost-effective manner possible and results in a market and price on
4 emissions that create incentives for the reduction of carbon pollution. The way allowances are
5 allocated in a cap and trade system is critical to its effectiveness and equity. Free allocations can be
6 provided to trade-exposed sectors such as agriculture either through historic allocations or output
7 based; the choice of which has important implications (Quirion 2009). Output based allocations may
8 be most suitable for agriculture also minimising leakage risk (see below) (Grosjean et al. 2018)
9 (Quirion 2009). There is *medium evidence* and *high agreement* that properly designed, a cap and
10 trade system can be a powerful policy instrument (Wagner 2013) and may collect more rents than a
11 variable carbon tax (Siegmeier et al. 2018; Schmalensee and Stavins 2017).

12 In the land sector carbon markets are challenging to implement. Although several countries and
13 regions have ETSs in place (for example the EU, Switzerland, the Republic of Korea, Quebec in
14 Canada, California in the USA (Narassimhan et al. 2018)), none have included non-CO₂ (methane and
15 nitrous oxide) emissions from agriculture. New Zealand is the only country currently considering
16 ways to incorporate agriculture into its ETS (see Case Study on the New Zealand Emissions Trading
17 Scheme).

18 Three main reasons explain the lack of implementation to date:

19 1. The large number of heterogeneous buyers and sellers, combined with the difficulties of
20 monitoring, reporting and verification (MRV) of emissions from biological systems introduce
21 potentially high levels of complexity (and transaction costs). Effective policies therefore depend on
22 advanced MRV systems which are lacking in many (particularly developing) countries (Wilkes et al.
23 2017). This is discussed in more detail in the Case Study on the New Zealand Emissions Trading
24 Scheme.

25 2. Adverse distributional consequences (Grosjean et al. 2018) (*medium evidence, high agreement*).
26 Distributional issues depend, in part, on the extent that policy costs can be passed on to consumers,
27 and there is *medium evidence* and *medium agreement* that social equity can be increased through a
28 combination of non-market and market-based instruments (Haites 2018b).

29 3. Regulation, market-based or otherwise, adopted in only one jurisdiction and not elsewhere may
30 result in ‘leakage’ or reduced effectiveness – where production relocates to weaker regulated regions,
31 potentially reducing the overall environmental benefit. Although modelling studies indicate the
32 possibility of leakage following unilateral agricultural mitigation policy implementation (e.g.
33 Fellmann et al. 2018), there is no empirical evidence from the agricultural sector yet available.
34 Analysis from other sectors shows an overestimation of the extent of carbon leakage in modelling
35 studies conducted before policy implementation compared to evidence after the policy was
36 implemented (Branger and Quirion 2014). Options to avoid leakage include border adjustments
37 (emissions in non-regulated imports are taxed at the border, and payments made on products exported
38 to non-regulated countries are rebated); differential pricing for trade-exposed products and; output
39 based allocation (which effectively works as a subsidy for trade-exposed products). Modelling shows
40 that border adjustments are the most effective at reducing leakage, but may exacerbate regional
41 inequality (Böhringer et al. 2012) and through their trade-distorting nature may contravene WTO
42 rules. The opportunity for leakage would be significantly reduced ideally through multi-lateral
43 commitments (Fellmann et al. 2018) (*medium evidence, high agreement*) but could also be reduced
44 through regional or bi-lateral commitments within trade agreements.

45

46

Case study: Including agriculture in the Emissions Trading Scheme in New Zealand

New Zealand has a high proportion of agricultural emissions at 49% (Ministry of the Environment 2018) - the next highest developed country agricultural emitter is Ireland at around 32% (EPA 2018) - and is considering to incorporate agricultural non-CO₂ gases into the existing national ETS. In the original design of the ETS in 2008, agriculture was intended to be included from 2013, but successive Governments deferred the inclusion (Kerr and Sweet 2008) due to concerns about competitiveness, lack of mitigation options and the level of opposition from those potentially affected (Cooper and Rosin 2014). Now though, as the country's agricultural emissions are 12% above 1990 levels, and the country's total gross emissions have increased 19.6% above 1990 levels (New Zealand Ministry for the Environment 2018), there is a recognition that without any targeted policy for agriculture, only 52% of the country's emissions face any substantive incentive to mitigate (Narassimhan et al. 2018). Including agriculture in the ETS is one option to provide incentives for emissions reductions in that sector. Other options are discussed in Section 7.4.4. Although some producer groups raise concern that including agriculture will place New Zealand producers at a disadvantage compared with their international competitors who do not face similar mechanisms (New Zealand Productivity Commission 2018), there is generally greater acceptance of the need for climate policies for agriculture.

The inclusion of non-CO₂ emissions from agriculture within an ETS is potentially complex however, due to the large number of buyers and sellers if obligations are placed at farm level, and different choices of how to estimate emissions from biological systems in cost-effective ways. New Zealand is currently investigating practical and equitable approaches to include agriculture through advice being provided by the Interim Climate Change Committee (ICCC 2018). Main questions centre around the point of obligation for buying and selling credits, where trade-offs have to be made between providing incentives for behaviour change at farm level and the cost and complexity of administering the scheme (Agriculture Technical Advisory Group 2009; Kerr and Sweet 2008). The two potential points of obligation are at the processor level or at the individual farm level. Setting the point of obligation at the processor level means that farmers would face limited incentive to change their management practices, unless the processors themselves rewarded farmers for lowered emissions. Setting it at the individual farm level would provide a direct incentive for farmers to adopt mitigation practices, however the reality of having thousands of individual points of obligation would be administratively complex and could result in high transaction costs (Beca Ltd 2018).

Monitoring, reporting and verification (MRV) of agricultural emissions presents another challenge especially if emissions have to be estimated at farm level. Again, trade-offs have to be made between accuracy and detail of estimation method and the complexity, cost and audit of verification (Agriculture Technical Advisory Group 2009).

The ICCC is also exploring alternatives to an ETS to provide efficient abatement incentives (ICCC 2018).

Some discussion in New Zealand also focuses on a differential treatment of methane compared to nitrous oxide, Methane is a short-lived gas with a perturbation lifetime of twelve years in the atmosphere; nitrous oxide on the other hand is a long-lived gas and remains in the atmosphere for 114 years (Allen et al. 2016). Long-lived gases have a cumulative and essentially irreversible effect on the climate (IPCC 2014b) so their emissions need to reduce to net-zero in order to avoid climate change. Short-lived gases however could potentially be reduced to a certain level and then stabilised and would not contribute further to warming, leading to suggestions of treating these two gases separately in the ETS or alternative policy instruments, possibly setting different budgets and targets for each (New Zealand Productivity Commission 2018). Reisinger et al. (2013) demonstrate that different metrics can have important implications globally and potentially at national and regional scales on the costs and levels of abatement.

While the details are still being agreed on in New Zealand, almost 80% of NDCs committed to action on mitigation in agriculture (FAO 2016), so countries will be looking for successful examples.

1 Australia's Emissions Reduction Fund, and the preceding Carbon Farming Initiative, are an example
2 of a baseline-and-credit scheme, which set an emissions intensity baseline and creates credits for
3 activities that generate emissions below the baseline, effectively a subsidy (Freebairn 2016). It is a
4 voluntary scheme, and has potential to create real and additional emission reductions through projects
5 reducing emissions and sequestering carbon (Verschuuren 2017) (*low evidence, low agreement*). Key
6 success factors in the design of such an instrument are policy-certainty for at least ten to twenty years,
7 regulation that focuses on projects and not uniform rules, automated systems for all phases of the
8 projects, and a wider focus of the carbon farming initiative on adaptation, food security, sustainable
9 farm business, and creating jobs (Verschuuren 2017). A recent review highlighted the issue of
10 permanence and reversal, and recommended that projects detail how they will maintain carbon in their
11 projects and deal with the risk of fire.

12 **7.4.4.3. Technology transfer and land use sectors**

13 Technology transfer has been part of the UNFCCC process since its inception and is a key element of
14 international climate mitigation and adaptation efforts under the Paris Agreement. The IPCC
15 definition of Technology transfer includes transfer of knowledge and technological cooperation (see
16 Glossary) and can include modifications to suit local conditions and/or integration with indigenous
17 technologies (Metz et al. 2000). This definition suggests greater heterogeneity in the applications for
18 climate mitigation and adaptation, especially in land use sectors where indigenous knowledge may be
19 important for long-term climate resilience Nyong et al. (2007). For land use sectors, the typical
20 reliance on trade and patent data for empirical analyses is generally not feasible as the "technology" in
21 question is often related to resource management and is neither patentable nor tradable (Glachant and
22 Dechezleprêtre 2017) and ill-suited to provide socially beneficially innovation for poorer farmers in
23 developing countries (Lybbert and Sumner 2012; Baker, Dean; Jayadev, Arjun; Stiglitz 2017).

24 Technology transfer has contributed to emissions reductions (*medium confidence*). A detailed study
25 for nearly 4000 Clean Development Mechanism (CDM) projects showed that 39% of projects had a
26 stated and actual technology transfer component, accounting for 59% of emissions reductions;
27 however, the more land-intensive projects (e.g., afforestation, bioenergy) showed lower percentages
28 (Murphy et al. 2015). Bioenergy projects that rely on agricultural residues offer substantially more
29 development benefits than those based on industrial residues from forests (Lee and Lazarus 2013).
30 Energy projects tended to have a greater degree of technology transfer under the CDM compared to
31 non-energy projects (Gandenberger et al. 2016). However, longer-term cooperation and collaborative
32 R&D approaches to technology transfer will be more important in land use sectors (compared to
33 energy or industry) due to the time needed for improved resource management and interaction
34 between researchers, practitioners and policy-makers. These approaches offer longer-term technology
35 transfer that is more difficult to measure compared to specific cooperation projects; empirical research
36 on the effects of R&D collaboration could help to avoid the "one-policy-fits-all" approach (Ockwell
37 et al. 2015).

38 There is increasing recognition of the role of technology transfer in climate adaptation, but in the land
39 use sector there are inherent adoption challenges specific to adaptation, due to uncertainties arising
40 from changing climatic conditions, agricultural prices, and suitability under future conditions (Biagini
41 et al. 2014). Engaging the private sector is important, as adoption of new technologies can only be
42 replicated with significant private sector involvement (Biagini and Miller 2013).

43 **7.4.4.4. International Cooperation under the Paris Agreement**

44 New cooperative mechanisms under the Paris Agreement illustrate the shift away from the Kyoto
45 Protocol's emphasis on obligations of developed country Parties to pursue investments and
46 technology transfer, to a more pragmatic, decentralised and collaborative approach (Savaresi 2016;
47 Jiang et al. 2017). These approaches can effectively include any combination of measures or
48 instruments related to adaptation, mitigation, finance, technology transfer and capacity-building,

1 which could be of particular interest in land use sectors where such aspects are more intertwined than
2 in energy or industry sectors. Article 6 sets out several options for international cooperation (Gupta
3 and Dube 2018).

4 The close relationship between emission reductions, adaptive capacity, food security and other
5 sustainability and governance objectives in the land sectors means that Article 6 could bring co-
6 benefits that increase its attractiveness and the availability of finance, while also bringing risks that
7 need to be monitored and mitigated against, such as uncertainties in measurements and the risk of
8 non-permanence (Thamo and Pannell 2016; Olsson et al. 2016; Schwartz et al. 2017). There has been
9 progress in accounting for land-based emissions, mainly forestry and agriculture (*medium evidence*,
10 *low agreement*), but various challenges remain (Macintosh 2012; Pistorius et al. 2017; Krug 2018).

11 Like the Clean Development Mechanism (CDM) and other existing carbon trading mechanisms,
12 participation in Article 6.2 and 6.4 of the Paris Agreement requires certain institutional and data
13 management capacities in the land sector to effectively benefit from the cooperation opportunities
14 (Totin et al. 2018). While the rules for the implementation of the new mechanisms are still under
15 development, lessons from REDD+ may be useful, which is perceived as more democratic and
16 participative than the CDM (Maraseni and Cadman 2015). Experience with REDD+ programs
17 emphasise the necessity to invest in “readiness” programs that assist countries to engage in strategic
18 planning and build management and data collection systems to develop the capacity and infrastructure
19 to participate in REDD+ (Minang et al. 2014). The overwhelming majority of countries (93%) cite
20 weak forest sector governance and institutions in their applications for REDD+ readiness funding
21 (Kissinger et al. 2012). Technology transfer for advanced remote sensing technologies that help to
22 reduce uncertainty in monitoring forests helps to achieve REDD+ “readiness” (Goetz et al. 2015).

23 As well as new opportunities for finance and support, the Paris cooperation mechanisms and the
24 associated roles for technology transfer bring new challenges, particularly in reporting, verifying and
25 accounting in land use sectors. Since developing countries must now achieve, measure and
26 communicate emission reductions, they now have value for both developing and developed countries
27 in achieving their NDCs, but reductions cannot be double-counted (i.e., towards multiple NDCs). All
28 countries have to prepare and communicate NDCs, and many countries have included in their NDCs
29 either economy-wide targets that include the land use sectors, or specific targets for the land use
30 sectors. The Katowice climate package clarifies that all Parties have to submit ‘Biennial
31 Transparency Reports’ from 2024 onwards using common reporting formats, following most recent
32 IPCC Guidelines (use of the 2013 Supplement on Wetlands is encouraged), identifying key categories
33 of emissions, ensuring time-series consistency, and providing completeness and uncertainty
34 assessments as well as quality control (UNFCCC 2018a; Schneider and La Hoz Theuer 2019). In
35 total, the ambiguity in how countries incorporate land use sectors into their NDC is estimated to lead
36 to an uncertainty of more than 2 GtCO₂ in 2030 (Fyson and Jeffery 2018). Uncertainty is lower if the
37 analysis is limited to countries that have provided separate land use sector targets in their NDCs
38 (Benveniste et al. 2018).

39 **7.4.5. Policies Responding to Desertification and Degradation – Land** 40 **Degradation Neutrality (LDN)**

41 Land degradation neutrality (LDN) (SDG Target 15.3), evolved from the concept of Net Zero Land
42 Degradation, which was introduced by the UNCCD to promote sustainable land management (Kust et
43 al. 2017; Stavi and Lal 2015; Chasek et al. 2015). Neutrality here implies no net loss of the land-based
44 natural resource and ecosystem services relative to a baseline or a reference state (UNCCD 2015;
45 Kust et al. 2017; Easdale 2016; Cowie et al. 2018a; Stavi and Lal 2015; Grainger 2015; Chasek et al.
46 2015). Land degradation neutrality can be achieved by reducing the rate of land degradation (and
47 concomitant loss of ecosystem services) and increasing the rate of restoration and rehabilitation of

1 degraded or desertified land. Therefore, the rate of global land degradation is not to exceed that of
 2 land restoration in order to achieve land degradation neutrality goals (adopted as national platform for
 3 actions by > 100 countries)(Stavi and Lal 2015; Grainger 2015; Chasek et al. 2015; Cowie et al.
 4 2018a; Montanarella 2015). Achieving land degradation neutrality would decrease the environmental
 5 footprint of agriculture, while supporting food security and sustaining human wellbeing (UNCCD
 6 2015; Safriel 2017; Stavi and Lal 2015; Kust et al. 2017).

7 Response hierarchy - avoiding, reducing and reversing land degradation - is the main policy response
 8 (Chasek et al. 2019, Wonder and Bodle 2019, Cowie et al. 2018, Orr et al. 2017). The LDN response
 9 hierarchy encourages through regulation, planning and management instruments, the adoption of
 10 diverse measures to avoid, reduce and reverse land degradation in order to achieve LDN (Cowie et al.
 11 2018b; Orr et al. 2017).

12
 13 **Figure 7.4 LDN response hierarchy**

14 **Source: Adapted from (Liniger et al. 2019; UNCCD/Science-Policy-Interface 2016)**

15
 16 Chapter 3 categorised policy responses into two categories; (1) avoiding, reducing and reversing it
 17 through sustainable land management; and (2) providing alternative livelihoods with economic
 18 diversification. Land degradation neutrality could be achieved through planned effective actions,
 19 particularly by motivated stakeholders those who play an essential role in a land-based climate change
 20 adaptation (Easdale 2016; Qasim et al. 2011; Cowie et al. 2018a; Salvati and Carlucci 2014). Human
 21 activities impacting the sustainability of drylands is a key consideration in adequately reversing
 22 degradation through restoration or rehabilitation of degraded land (Easdale 2016; Qasim et al. 2011;
 23 Cowie et al. 2018a; Salvati and Carlucci 2014).

24 LDN actions and activities play an essential role for a land-based approach to climate change
 25 adaptation (UNCCD 2015). Policies responding to degradation and desertification include improving
 26 market access, gender empowerment, expanding access to rural advisory services, strengthening land
 27 tenure security, payments for ecosystem services, decentralised natural resource management,
 28 investing into research and development, investing into monitoring of desertification and desert
 29 storms, developing modern renewable energy sources, investing into modern renewable energy
 30 sources, and developing and strengthening climate services. Policy supporting economic
 31 diversification include investing in irrigation, expanding agricultural commercialisation, and
 32 facilitating structural transformations in rural economies. (Chapter 3). Policies and actions also
 33 include promoting local and indigenous knowledge, soil conservation, agroforestry, crop-livestock
 34 interactions as an approach to manage land degradation, and forest based activities such as
 35 afforestation, reforestation, and changing forest management (Chapter 4). Measures identified for
 36 achievement of LDN include; effective financial mechanisms (for implementation of land restoration
 37 measures and the long-term monitoring of progress), parameters for assessing land degradation,

1 detailed plans with quantified objectives and timelines (Kust et al. 2017; Sietz et al. 2017; Cowie et al.
2 2018a; Montanarella 2015; Stavi and Lal 2015).

3 Implementing the international LDN target into national policies has been a challenge (Cowie et al.
4 2018a; Grainger 2015) as baseline land degradation or desertification information is not always
5 available (Grainger 2015) and challenges exist in monitoring LDN as it is a dynamic process (Sietz et
6 al. 2017; Grainger 2015; Cowie et al. 2018a). Wunder and Bodle (2019) propose that LDN be
7 implemented and monitored through indicators at the national level. Effective implementation of
8 global LDN will be supported by integrating lessons learned from existing programs designed for
9 other environmental objectives and closely coordinate LDN activities with actions for climate change
10 adaptation and mitigation at both global and national levels (*high confidence*) (Stavi and Lal 2015;
11 Grainger 2015).

12

13 **7.4.6. Policies Responding to Land Degradation**

14 **7.4.6.1. Land Use Zoning**

15 Land use zoning divides a territory (including local, sub-regional or national) into zones with different
16 rules and regulations for land use (mining, agriculture, urban development etc.), management
17 practices and land cover change (Metternicht 2018). While the policy instrument is zoning
18 ordinances, the process of determining these regulations is covered in integrated land use planning
19 (See 7.6.2). Urban zoning can guide new growth in urban communities outside current and
20 forecasted hazard areas, assist relocating existing dwellings to safer sites and manage postevent
21 redevelopment in ways to reduce future vulnerability (Berke and Stevens 2016). Holistic integration
22 of climate mitigation and adaptation are interdependent and can be implemented by restoring urban
23 forests, improving parks (Brown 2010; Berke and Stevens 2016). Zoning ordinances can contribute to
24 sustainable land management through protection of natural capital by preventing or limiting
25 vegetation clearing, avoiding degradation of planning for rehabilitation of degraded land or
26 contaminated sites, promoting conservation and enhancement of ecosystems and ecological corridors
27 (Metternicht 2018; Jepson and Haines 2014). Zoning ordinances can also encourage higher density
28 development, mixed use, local food production, encourage transportation alternatives (bike paths and
29 transit oriented development), preserve a sense of place, and increase housing diversity and
30 affordability (Jepson and Haines 2014). Conservation planning varies by context and may include one
31 or several adaptation approaches including protecting current patterns of biodiversity, large intact
32 natural landscapes, and geophysical settings. Conservation planning may also maintain and restore
33 ecological connectivity, identify and manage areas that provide future climate space for species
34 expected to be displaced by climate change, and identify and protect climate refugia (Stevanovic et
35 al. 2016; Schmitz et al. 2015).

36 Anguelovski et al. (2016) studied land use interventions in eight cities in the global north and south
37 and concluded that historic trends of socioeconomic vulnerability can be reinforced which could be
38 avoided with a consideration of the distribution of adaptation benefits and prioritising beneficial
39 outcomes for disadvantaged and vulnerable groups when making future adaptation plans.
40 Concentration of adaptation resources within wealthy business districts creating ecological enclaves
41 exacerbated climate risks elsewhere and building of climate adaptive infrastructure such as sea walls
42 or temporary flood barriers occurred at the expense of underserved neighbourhoods (Anguelovski et
43 al. 2016a).

44

45 **7.4.6.2. Conserving biodiversity and ecosystem services**

46 There is *limited evidence but high agreement* that ecosystem-based adaptation (biodiversity,
47 ecosystem services, and nature's contribution to people (see chapter 6)) and incentives for ecosystem

1 services (including PES) play a critical part of an overall strategy to help people adapt to the adverse
2 effects of climate change on land (UNEP 2009) (Bonan 2008; Millar et al. 2007; Thompson et al.
3 2009).

4
5 Ecosystem based adaptation can promote socio-ecological resilience by enabling people to adapt to
6 the impacts of climate change on land and reduce their vulnerability (Ojea 2015). Ecosystem based
7 adaptation can promote nature conservation while alleviating poverty and even provide co-benefits by
8 removing greenhouse gas (Scarano 2017) and protecting livelihoods (Munang et al. 2013). For
9 example, mangroves provide diverse ecosystem services such as carbon storage, fisheries, non-timber
10 forest products, erosion protection, water purification, shore-line stabilisation and also regulate storm
11 surge and flooding damages, thus enhancing resilience and reducing climate risk from extreme events
12 such as cyclones (Rahman, M.M., Khan, M.N.I., Hoque, A.K.F., Ahmed 2014; Donato et al. 2011;
13 Das and Vincent 2009; Ghosh et al. 2015; Ewel et al. 1998).

14
15 There has been considerable increase in the last decade of payments for ecosystem services (PES), or
16 programmes that exchange value for land management practices intended to ensure ecosystem
17 services (Salzman et al. 2018; Yang and Lu 2018; Barbier 2011). However, there is a deficiency in
18 comprehensive and reliable data concerning PES' impact on ecosystems, human well-being, their
19 efficiency, and effectiveness (Pynegar et al. 2018; Reed et al. 2014; Salzman et al. 2018; Barbier
20 2011; Yang and Lu 2018). While some studies assess ecological effectiveness and social equity,
21 fewer assess economic efficiency (Yang and Lu 2018). Part of the challenge surrounds the fact that
22 the majority of ecosystem services are not marketed, so determining how changes in ecosystems
23 structures, functions and processes influence the quantity and quality of ecosystem service flows to
24 people is challenging (Barbier 2011). PES include agri-environmental targeted outcome based
25 payments, but challenges exist in relation to scientific uncertainty, pricing, timing of payments,
26 increasing risk to land managers, World Trade Organization compliance, and barriers of land
27 management and scale (Reed et al. 2014).

28
29 PES is contested (Wang and Fu 2013; Czembrowski and Kronenberg 2016) (Perry 2015) for four
30 reasons: (1) understanding and resolving trade-offs between conflicting groups of stakeholders (Wam
31 et al. 2016) (Matthies et al. 2015); (2) knowledge and technology capacity (Menz et al. 2013); (3)
32 challenges integrating PES with economic and other policy instruments (Ring and Schröter-Schlaack
33 2011; Tallis et al. 2008)(Elmqvist et al. 2003; Albert et al. 2014); and (4) top down climate change
34 mitigation initiatives which are still largely carbon centric with limited opportunities for decentralised
35 ecological restoration at local and regional scales (Vijge and Gupta 2014).

36
37 These challenges and contestations can be resolved with the participation of people in establishing
38 PES thereby addressing trust issues, negative attitudes, and resolving trade-offs between issues (such
39 as retaining forests that consume water versus the provision of run off, or balancing payments to
40 providers versus cost to society) (Sorice et al. 2018; Matthies et al. 2015). Similarly, a 'co-
41 constructive' approach is used involving a diversity of stakeholders generating policy relevant
42 knowledge for sustainable management of biodiversity and ecosystem services at all relevant spatial
43 scales, by the current Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem
44 Services (IPBES) initiative (Díaz et al. 2015). Invasive species are also best identified and managed
45 with the participation of people through collective decisions, coordinated programs, and extensive
46 research and outreach to address their complex social-ecological impacts (Wittmann et al. 2016;
47 Epanchin-Niell et al. 2010).

48
49 Ecosystem restoration with co-benefits for diverse ecosystem services can be achieved through
50 passive restoration, passive restoration with protection and active restoration with planting (Birch et
51 al. 2010; Cantarello et al. 2010). Taking into account costs of restoration and co-benefits from bundles
52 of ecosystem services (carbon, tourism, timber), the benefit cost ratio of active restoration and passive
53 restoration with protection was always less than 1, suggesting that financial incentives would be
54 required. Passive restoration was the most cost-effective with BCR was generally between 1 and 100
55 for forest, grassland and shrubland restoration (TEEB 2009; Cantarello et al. 2010). Passive

1 restoration is generally more cost-effective but there is a danger that it could be confused with
2 abandoned land in the absence of secure tenure and long time period (Zahawi et al. 2014). Net Social
3 Benefits of degraded land restoration in dry regions range from about 200–700 USD per hectare
4 (Cantarello et al., 2010). Investments in active restoration could benefit from analyses of past land
5 use, the natural resilience of the ecosystem, and the specific objectives of each project (Meli et al.
6 2017). One successful example is the Working for Water initiative in South Africa that linked
7 restoration through removal of invasive species and enhancing water security (Milton et al. 2003).

8
9 Forest, water and energy cycle interactions and teleconnections such as contribution to rainfall
10 potentially (2.5.4) (Aragão 2012; Ellison et al. 2017; Paul et al. 2018; Spracklen et al. 2012) provide a
11 foundation for achieving forest-based adaptation and mitigation goals. They are however poorly
12 integrated in policy and decision making including PES.

13 14 15 **7.4.6.3. Standards and certification for sustainability of biomass and land use** 16 **sectors**

17 During the past two decades, standards and certification have emerged as important sustainability and
18 conservation instruments for agriculture, forestry, bioenergy, land use management and bio-based
19 products (Lambin et al. 2014; Englund and Berndes 2015; Milder et al. 2015; Giessen et al. 2016a;
20 Endres et al. 2015; Byerlee et al. 2015; van Dam et al. 2010). Standards are normally voluntary but
21 can also become obligatory through legislation. A standard provides specifications or guidelines to
22 ensure that materials, products, processes and services are fit for their purpose, whereas certification is
23 the procedure through which an accredited party confirms that a product, process or service is in
24 conformity with certain standards. Standards and certification are normally carried out by separate
25 organisations for legitimacy and accountability (see 7.6.6). The International Organization for
26 Standardization (ISO) is a key source for global environmental standards. Those with special
27 relevance for land and climate include a recent standard on combating land degradation and
28 desertification (ISO 2017) and an earlier standard on sustainable bioenergy and biomass use (ISO
29 2015; Walter et al. 2018). Both aim to support the long-term transition to a climate-resilient
30 bioeconomy; there is *medium evidence* on the sustainability implications of different bioeconomy
31 pathways, but *low agreement* as to which pathways are socially and environmentally desirable
32 (Priefer et al. 2017; Johnson 2017; Bennich et al. 2017a).

33 Table 7.3 provides a summary of selected standards and certification schemes with a focus on land use
34 and climate: the tickmark shows inclusion of different sustainability elements, with all recognising the
35 inherent linkages between the biophysical and social aspects of land use. Some certification schemes
36 and best practice guidelines are specific to a particular agriculture crop (e.g., soya, sugarcane) or a
37 tree (oil palm) while others are general. International organisations promote sustainable land and
38 biomass use through good practice guidelines, voluntary standards and jurisdictional approaches
39 (Scarlat and Dallemand 2011; Stattman et al. 2018a; ISEAL Alliance). Other frameworks, such as the
40 Global Bioenergy Partnership (GBEP) focus on monitoring land and biomass use through a set of
41 indicators that are applied across partner countries, thereby also promoting technology (knowledge)
42 transfer (GBEP 2017). The Economics of Land Degradation Initiative (ELD) provides common
43 guidelines for economic assessments of land degradation (Nkonya et al. 2013).

44 Whereas current standards and certification focus primarily on land, climate and biomass impacts
45 where they occur, more recent analysis considers trade-related land use change by tracing supply
46 chain impacts from producer to consumer, leading to the notion of “imported deforestation” that
47 occurs from increasing demand and trade in unsustainable forest and agriculture products, which is
48 estimated to account for 26% of all tropical deforestation (Pendrill et al. 2019). Research and
49 implementation efforts aim to improve supply chain transparency and promote commitments to “zero
50 deforestation” (Gardner et al. 2018a; Garrett et al. 2019; Newton et al. 2018; Godar and Gardner
51 2019; Godar et al. 2015, 2016). France has developed specific policies on imported deforestation that
52 are expected to eventually include a zero deforestation label (Government of France 2019).

Table 7.3 Selected standards and certification schemes and their components or coverage

Acronym	Scheme, programme or standard	Commodity/process, relation to others	Type of mechanism	Environmental						Socio-economic		
				GHG emissions	Biodiversity	Carbon stock	Soil	Air	Water	Land use management ^a	Land rights	Food security ^b

ISO 14055-1: 2017	Land Degradation and Desertification	land use management, including restoration of degraded land	Standard	√				√	√	√	√	

Source: Modified from (European Commission 2012; DIAZ-CHAVEZ 2015).

√ indicates that the issue is addressed in the standard or scheme

^a includes restoration of degraded land in some cases (especially ISO 14055-1)

^b where specifically indicated

^c reference to the RSB certification/standard

^d where specifically noted

1 The sustainability of biofuels and bioenergy has been in particular focus during the past decade or so
2 due to biofuel mandates and renewable energy policies in the U.S., EU and elsewhere (van Dam et al.
3 2010; Scarlat and Dallemand 2011). The European Union Renewable Energy Directive (EU-RED)
4 established sustainability criteria in relation to EU renewable energy targets in the transport sector
5 (European Commission 2012), which subsequently had impacts on land use and trade with third-party
6 countries (Johnson et al. 2012). In particular, the EU-RED marked a departure in the context of
7 Kyoto/UNFCCC guidelines by extending responsibility for emissions beyond the borders of final use,
8 and requiring developing countries wishing to sell into the EU market to meet the sustainability
9 criteria (Johnson 2011b). The recently revised EU-RED provides sustainability criteria that include
10 management of land and forestry as well as socio-economic aspects (European Union 2018; Faaij
11 2018; Stattman et al. 2018b). Standards and certification aim to address potential conflicts between
12 different uses of biomass and most schemes also consider co-benefits and synergies (see Cross-
13 chapter Box 7: Bioenergy and BECCS in mitigation scenarios, in Chapter 6). Bioenergy may offer
14 additional income and livelihoods to farmers as well as improvements in technical productivity and
15 multi-functional landscapes (Rosillo Callé and Johnson 2010a; Kline et al. 2017; Araujo Enciso et al.
16 2016). Results depend on the commodities involved, and also differ between rural and urban areas.

17 Analyses on the implementation of standards and certification for land and biomass use have focused
18 on their stringency, effectiveness and geographical scope as well as socio-economic impacts such as
19 land tenure, gender and land rights (Diaz-Chavez 2011; German and Schoneveld 2012; Meyer and
20 Priess 2014). The level of stringency and enforcement varies with local environmental conditions,
21 governance approaches and the nature of the feedstock produced (Endres et al. 2015; Lambin et al.
22 2014; Giessen et al. 2016b; Stattman et al. 2018b). There is *low evidence and low agreement* on how
23 the application and use of standards and certification has actually improved sustainability beyond the
24 local farm, factory or plantation level; the lack of harmonisation and consistency across countries that
25 has been observed, even within a common market or economic region such as the EU, presents a
26 barrier to wider market impacts (Endres et al. 2015; Stattman et al. 2018b; ISEAL Alliance). In the
27 forest sector, there is evidence that certification programmes such as FSC have reduced deforestation
28 in the aggregate as well as reducing air pollution (Miteva et al. 2015; Mcdermott et al. 2015).
29 Certification and standards cannot address global systemic concerns such as impacts on food prices or
30 other market-wide effects but rather are aimed primarily at insuring best practices in the local context.
31 More general approaches to certification such as the Gold Standard are designed to accelerate
32 progress toward the SDGs as well as the Paris Climate Agreement by certifying investment projects
33 while also emphasising support to governments (Gold Standard).

34

7.4.6.4. Energy access and biomass use

Access to modern energy services is a key component of SDG 7, with an estimated 1.1 billion persons lacking access to electricity while nearly three billion people relying on traditional biomass (fuelwood, agriculture residues, animal dung, charcoal) for household energy needs (IEA 2017). Lack of access to modern energy services is significant in the context of land-climate systems because heavy reliance on traditional biomass can contribute to land degradation, household air pollution and GHG emissions (see Cross Chapter box 12: Traditional Biomass use, in this Chapter). A variety of policy instruments and programmes have been aimed at improving energy access and thereby reducing the heavy reliance on traditional biomass (see Table 7.2); there is *high evidence and high agreement* that programmes and policies that reduce dependence on traditional biomass will have benefits for health and household productivity as well as reducing land degradation (see section 4.5.4) and GHG emissions (Bailis et al. 2015; Cutz et al. 2017a; Masera et al. 2015; Goldemberg et al. 2018a; Sola et al. 2016a; Rao and Pachauri 2017; Denton et al. 2014). There can be trade-offs across different options, especially between health and climate benefits since more efficient wood stoves might have only limited effect, whereas gaseous and liquid fuels (e.g., biogas, LPG, bioethanol) will have highly positive health benefits and climate benefits that vary depending on specific circumstances of the substitution (Cameron et al. 2016; Goldemberg et al. 2018b). Unlike traditional biomass, modern bioenergy offers high quality energy services, although for household cookstoves, even the cleanest options using wood may not perform as well in terms of health and/or climate benefits (Fuso Nerini et al. 2017; Goldemberg et al. 2018b).

Case Study: Forest conservation instruments: REDD+ in the Amazon and India

Over 50 countries have developed national REDD+ strategies, which have key conditions for addressing deforestation and forest degradation (improved monitoring capacities, understanding of drivers, increased stakeholder involvement, and provided a platform to secure indigenous and community land rights), however to achieve its original objectives and to be effective under current conditions, forest-based mitigation actions need to be incorporated in national development plans and official climate strategies, and mainstreamed across sectors and levels of government (Angelsen et al. 2018a).

The Amazon region can illustrate the complexity of the implementation of REDD+, in the most biodiverse place of the planet, with millions of inhabitants and hundreds of ethnic groups, under the jurisdiction of eight countries. While different experiences can be drawn at different spatial scales, at the regional-level, for example, Amazon Fund (van der Hoff et al. 2018), at the subnational level (Furtado 2018), and at the local level (Alvarez et al. 2016; Simonet et al. 2019), there is *medium evidence and high agreement* that REDD+ has stimulated sustainable land-use investments but also is competing with other land uses (e.g., agroindustry) and scarce international funding (both public and private) (Bastos Lima et al. 2017b; Angelsen et al. 2018b)

In the Amazon, at the local level, a critical issue has been the incorporation of indigenous people in the planning and distribution of benefits of REDD+ projects. While REDD+, in some cases, has enhanced participation of community members in the policy-planning process, fund management, and carbon baseline establishment increased project reliability and equity (West 2016), it is clear that, in this region, insecure and overlapping land rights, as well as unclear and contradictory institutional responsibilities, are probably the major problems for REDD+ implementation (Loaiza et al. 2017). Despite legal and rhetoric recognition of indigenous land rights, effective recognition is still lacking (Aguilar-Støen 2017). The key to the success of REDD+ in the Amazon, has been the application of both, incentives and disincentives on key safeguard indicators, including land security, participation, and well-being (Duchelle et al. 2017).

1 On the other hand, at the subnational level, REDD+ has been unable to shape land-use dynamics or
2 landscape governance, in areas suffering strong exogenous factors, such as extractive industries, and
3 in the absence of effective regional regulation for sustainable land use (Rodriguez-Ward et al. 2018;
4 Bastos Lima et al. 2017b). Moreover, projects with weak financial incentives, engage households with
5 high off-farm income, which already are better off than the poorest families (Loaiza et al. 2015).
6 Beyond, operational issues, clashing interpretations of results might bring clashes between
7 implementing countries or organisations and donor countries, which have revealed concerns over the
8 performance of projects (van der Hoff et al. 2018)

9 REDD+ Amazonian projects often face methodological issues, including how to assess the
10 opportunity cost among landholders, and informing REDD+ implementation (Kweka et al. 2016).
11 REDD+ based projects depend on consistent environmental monitoring methodologies for measuring,
12 reporting and verification and, in the Amazon, land cover estimates are crucial for environmental
13 monitoring efforts (Chávez Michaelsen et al. 2017).

14 In India forests and wildlife concerns are on the concurrent list of the Constitution since an
15 amendment in 1976 thus giving the central or federal government a strong role in matters related to
16 governance of forests. High rates of deforestation due to development projects led to the Forest
17 (Conservation) Act (1980) which requires central government approval for diversion of forest land in
18 any state or union territory.

19 Before 2006 forest diversion for development projects leading to deforestation needed the forest
20 clearance from the Central Government under the provisions of the Forest (Conservation Act) 1980.
21 In order to regulate forest diversion and as payment for ecosystem services a Net Present Value
22 (NPV) frame-work was introduced by the Supreme Court of India informed by the Kanchan Chopra
23 committee (Chopra 2017). The Supreme Court established the Compensatory Afforestation
24 Management and Planning Authority (CAMPA) under which the fund collected for compensatory
25 afforestation and on account of NPV from project developers is deposited. The Forest (Conservation)
26 Act of 1980 does require compensatory afforestation in lieu of forest diversion and in addition after
27 CAMPA the payment of NPV to get the forest clearance for diversion has been added.

28 As of February 2018, USD 6,825 million had accumulated in CAMPA funds in lieu of NPV paid by
29 developers diverting forest land throughout India for non-forest use. Funds are released by the central
30 government to state governments out of this fund for afforestation and conservation related activities
31 to “compensate” for diversion of forests. This is now governed by legislation called CAMPA Act
32 passed by the Parliament of India in July 2016. The CAMPA mechanism has however invited
33 criticism on various counts in terms of undervaluation of forest, inequality, lack of participation and
34 environmental justice (Temper and Martinez-Alier 2013).

35 The other significant development related to forest land was the landmark legislation called the
36 Scheduled Tribes and Other Traditional Forest Dwellers (Recognition of Forest Rights) Act, 2006 or
37 Forest Rights Act passed by the Parliament of India in 2007. This is the largest forest tenure legal
38 instrument in the world and attempted to undo a historical injustice to forest dwellers and forest
39 dependent communities whose traditional rights and access were legally denied under forest and
40 wildlife conservation laws. The FRA recognises the right to individual land titles on land already
41 cleared as well as community forest rights such as collection of forest produce. Till November 2018, a
42 total of 64,328 community forest rights and a total of 17,040,343 individual land titles had been
43 approved and granted up to the end of 2017. Current concerns on policy and implementation gaps are
44 about strengths and pitfalls of decentralisation, identifying genuine right holders, verification of land
45 rights using technology and best practices, and curbing illegal claims (Sarap et al. 2013; Reddy et al.
46 2011; Aggarwal 2011; Ramnath 2008; Ministry of Environment and Forests and Ministry and Tribal
47 Affairs, Government of India 2010).

1 As per the FRA, the forest rights shall be conferred free of all encumbrances and procedural
2 requirements. Furthermore, without implementation of the provision of FRA on getting the informed
3 consent of local communities for both diversion of community forest land as well as for reforestation,
4 it poses legal and administrative hurdles in using existing forest land for implementation of India's
5 ambitious Green India Mission that aims to respond to climate change by a combination of adaptation
6 and mitigation measures in the forestry sector. It aims to increase forest/tree cover to the extent of 5
7 million hectares (Mha) and improve quality of forest/tree cover on another 5 Mha of forest/non-forest
8 lands and support forest based livelihoods of 3 million families and generate co-benefits through
9 ecosystem services (Government of India).

10 Thus, the community forest land recognised under FRA can be used for the purpose of Compensatory
11 Afforestation or restoration under REDD+ only with informed consent of the communities and a
12 decentralised mechanism for using CAMPA funds. India's forest and forest restoration can potentially
13 move away from a top-down carbon centric model with the effective participation of local
14 communities (Vijge and Gupta 2014; Murthy et al. 2018a).

15 India has also experimented with the world's first national inter-governmental ecological fiscal
16 transfer (EFT) from central to local and state government to reward them for retaining forest cover.
17 In 2014, India's 14th Finance Commission added forest cover to the formula that determines the
18 amount of tax revenue the central government distributes annually to each of India's 29 states. It is
19 estimated that in four years it would have distributed USD 6.9–12 billion per year to states in
20 proportion to their 2013 forest cover, amounting to around USD 174– 303 per hectare of forest per
21 year (Busch and Mukherjee 2017). State governments in India now have a sizeable fiscal incentive
22 based on extent of forest cover at the time of policy implementation contributing to the achievement
23 of India's climate mitigation and forest conservation goals. India's tax revenue distribution reform has
24 created the world's first EFTs for forest conservation, and a potential model for other countries.
25 However, it is to be noted that EFT is calculated based on a one-time estimate of forest cover prior to
26 policy implementation, hence does not incentivise ongoing protection and this is a policy gap. It's
27 still too early but its impact on trends in forest cover in the future and its ability to conserve forests
28 without other investments and policy instruments is promising but untested (Busch and Mukherjee
29 2017; Busch 2018).

30 In order to build on the new promising policy developments on forest rights and fiscal incentives for
31 forest conservation in India, incentivising ongoing protection, further investments in monitoring
32 (Busch 2018), decentralisation (Somanathan et al. 2009) and promotion of diverse non-agricultural
33 forest and range land based livelihoods (e.g., sustainable non-timber forest product extraction,
34 regulated pastures, carbon credits for forest regeneration on marginal agriculture land and ecotourism
35 revenues) as part of individual and community forest tenure and rights are ongoing concerns.
36 Decentralised sharing of CAMPA funds between government and local communities for forest
37 restoration as originally suggested and filling in implementation gaps could help reconcile climate
38 change mitigation through forest conservation, REDD+ and environmental justice (Vijge and Gupta
39 2014; Temper and Martinez-Alier 2013; Badola et al. 2013; Sun and Chaturvedi 2016; Murthy et al.
40 2018b; Chopra 2017; Ministry of Environment and Forests and Ministry and Tribal Affairs,
41 Government of India 2010).

7.4.7. Economic and financial instruments for adaptation, mitigation, and land

44 There is an urgent need to increase the volume of climate financing and bridge the gap between global
45 adaptation needs and available funds (*medium confidence*) (Valérie Masson-Delmotte et al. 2018;
46 Kissinger et al. 2019; Chambwera and Heal 2014), especially in relation to agriculture (FAO 2010).
47 The land sector offers the potential to balance the synergies between mitigation and adaptation

1 (Locatelli et al. 2016) (although context and unavailability of data sets makes cost comparisons
2 between mitigation and adaptation difficult (UNFCCC 2018b)). Estimates of adaptation costs range
3 from USD 140 to 300 billion by 2030, and between USD 280 and 500 billion by 2050; (UNEP 2016).
4 These figures vary according to methodologies and approaches (de Bruin et al. 2009; IPCC 2014
5 2014; Organization for Economic Cooperation and Development 2008; Nordhaus 1999; UNFCCC
6 2007; Plambeck et al. 1997).

7 **7.4.7.1. Financing mechanisms for land mitigation and adaptation**

8 A startling array of diverse and fragmented climate finance sources exist: more than 50 international
9 public funds, 60 carbon markets, 6000 private equity funds, 99 multilateral and bilateral climate funds
10 (Samuwal and Hills 2018). Most public finance for developing countries flows through bilateral and
11 multilateral institutions such as the World Bank, the International Monetary Fund, International
12 Finance Corporation, regional development banks, as well as specialised multilateral institutions such
13 as the Global Environmental Fund, and the EU Solidarity Fund. Some governments have established
14 state investment banks (SIBs) to close the financing gap, including the UK (Green Investment Bank),
15 Australia (Clean Energy Finance Corporation) and in Germany (Kreditanstalt für Wiederaufbau) the
16 Development Bank has been involved in supporting low-carbon finance (Geddes et al. 2018). The
17 Green Climate Fund (GCF) now offers additional finance, but is still a new institution with policy
18 gaps, a lengthy and cumbersome process related to approval (Brechtin and Espinoza 2017; Khan and
19 Roberts 2013; Mathy and Blanchard 2016), and challenges with adequate and sustained funding
20 (Schalatek and Nakhoda 2013). Private adaptation finance exists, but is difficult to define, track, and
21 coordinate (Nakhoda et al. 2016).

22 The amount of funding dedicated to agriculture, land degradation or desertification is very small
23 compared to total climate finance (FAO 2010). Funding for agriculture is accessed through the
24 smaller adaptation funds (rather than mitigation) (Lobell et al. 2013). Focusing on synergies, between
25 mitigation, adaptation, and increased productivity, such as through Climate Smart Agriculture
26 (CSA)(see 7.5.6), (Lipper et al. 2014b), may leverage greater financial resources (Suckall et al. 2015;
27 Locatelli et al. 2016). Payments for Ecosystem Services (see 7.4.6) are another emerging area to
28 encourage environmentally desirable practices, although they need to be carefully designed to be
29 effective (Engel and Muller 2016).

30 The UNCCD established the Land Degradation Neutrality Fund (LDN Fund) to mobilise finance and
31 scale up land restoration and sustainable business models on restored land to achieve the target of a
32 land degradation neutral world (SDG target 15.3) by 2030. The LDN Fund generates revenues from
33 sustainable use of natural resources, creating green job opportunities, sequestering CO₂, and
34 increasing food and water security (Cowie et al. 2018a; Akhtar-Schuster et al. 2017). The fund
35 leverages public money to raise private capital for sustainable land management and land restoration
36 projects (Quatrini and Crossman 2018; Stavi and Lal 2015). Many small-scale projects are
37 demonstrating that sustainable landscape management (see 7.6.3) is key to achieving LDN, and it is
38 also more financially viable in the long term than the unsustainable alternative (Tóth et al. 2018; Kust
39 et al. 2017).

40 **7.4.7.2. Instruments to manage the financial impacts of climate and land change** 41 **disruption**

42 Comprehensive risk management (see 7.4.3.1) designs a portfolio of instruments which are used
43 across a continuum of preemptive, planning and assessment, and contingency measures in order to
44 bolster resilience (Cummins and Weiss 2016) and address limitations of any one instrument
45 (Surminski 2016; Surminski et al. 2016; Linnerooth-bayer et al. 2019). Instruments designed and
46 applied in isolation have shown short-term rather than sustained intended impacts (Vincent et al.
47 2018). Risk assessments limited to events and impacts on particular asset classes or sectors can
48 misinform policy and drive misallocation of funding (Gallina et al. 2016; Jongman et al. 2014).

49 Comprehensive risk assessment combined with risk layering approaches that assign different
50 instruments to different magnitude and frequency of events, have better potential to provide stability

1 to societies facing disruption (Mechler et al. 2014; Surminski et al. 2016). Governments and citizens
2 define limits of what they consider acceptable risks, risks for which market or other solutions can be
3 developed and catastrophic risks that require additional public protection and intervention. Different
4 financial tools may be used for these different categories of risk or phases of the risk cycle
5 (preparedness, relief, recovery, reconstruction).

6 In order to protect lives and livelihoods early action is critical, including a coordinated plan for action
7 agreed in advance, a fast, evidence-based decision-making process, and contingency financing to
8 ensure that the plan can be implemented (Clarke and Dercon 2016a). Forecast-based finance
9 mechanisms incorporate these principles, using climate or other indicators to trigger funding and
10 action prior to a shock (Wilkinson 2018). Forecast-based mechanisms can be linked with social
11 protection systems by providing contingent scaled-up finance quickly to vulnerable populations
12 following disasters, enhancing scalability, timeliness, predictability and adequacy of social protection
13 benefits (Wilkinson 2018; Costella et al. 2017b; World Food Programme 2018).

14 Measures in advance of risks set aside resources before negative impacts related to adverse weather,
15 climatic stressors, and land changes occur. These tools are frequently applied in extreme event, rapid
16 onset contexts. These measures are the main instruments for reducing fatalities and limiting damage
17 from extreme climate and land change events (Surminski et al. 2016). Finance tools in advance of risk
18 include insurance (macro, meso, micro), green bonds, and forecast based finance (Hunzai et al. 2018).

19 There is *high confidence* that insurance approaches which are designed to effectively reduce and
20 communicate risks to the public and beneficiaries, designed to reduce risk and foster appropriate
21 adaptive responses, and provide value in risk transfer, improve economic stability and social
22 outcomes in both higher and lower income contexts (Kunreuther and Lyster 2016; Outreville
23 2011b)(Surminski et al. 2016; Kousky et al. 2018b), bolster food security, helping keep children in
24 school, and helping safeguard the ability of low income households to pay for essentials like
25 medicines (Shiferaw et al. 2014; Hallegatte et al. 2017).

26 Low income households show demand for affordable risk transfer tools, but demand is constrained by
27 liquidity, lack of assets, financial and insurance literacy, or proof of identity required by institutions in
28 the formal sector (Eling et al. 2014; Cole 2015; Cole et al. 2013; Ismail et al. 2017). Microinsurance
29 participation takes many forms including through mobile banking (Eastern Africa, Bangladesh),
30 linked with social protection or other social stabilisation programs (Ethiopia, Pakistan, India), through
31 flood or drought protection schemes (Indonesia, the Philippines, the Caribbean, and Latin America),
32 often in the form of weather index insurance. Insurance faces challenges around low public
33 awareness of how insurance works, risk, low capacity in financial systems to administer insurance,
34 data deficits, and market imperfections (Mechler et al. 2014; Feyen et al. 2011; Gallagher 2014;
35 Kleindorfer et al. 2012; Lazo et al.; Meyer and Priess 2014; Millo 2016).

36 Countries also request grant assistance, and contingency debt finance that includes dedicated funds,
37 set aside for unpredictable climate-related disasters, household savings, loans with “catastrophe risk
38 deferred drawdown option” (CATDDO) (which allows countries to divert loans from development
39 objectives such as health, education, and infrastructure to make immediate disbursement of funds in
40 the event of a disaster) (Kousky and Cooke 2012; Clarke and Dercon 2016b). Contingency finance is
41 suited to manage frequently occurring, low-impact events (Campillo et al. 2017; Mahul and
42 Ghesquiere 2010; Roberts 2017) and may be linked with social protection systems. These instruments
43 are limited by uncertainty surrounding the size of contingency fund reserves, given unpredictable
44 climate disasters (Roberts 2017) and lack of borrowing capacity of a country (such as small island
45 states) (Mahul and Ghesquiere 2010).

46 In part because of its link with debt burden, contingency, or post event finance can disrupt
47 development and is not suitable for higher consequence events and processes such as weather
48 extremes or structural changes associated with climate and land change. Post event finance of
49 negative impacts such as sea level rise, soil salinisation, depletion of groundwater, and widespread
50 land degradation is likely to become infeasible for multiple, high cost events and processes. There is
51 *high confidence* post-extreme event assistance may face more severe limitations given impacts of

1 climate change (Linnerooth-bayer et al. 2019; Surminski et al. 2016; Deryugina 2013; Dillon et al.
2 2014; Clarke 2016; Shreve and Kelman 2014; Von Peter et al. 2012).

3 In a catastrophe risk pool, multiple countries in a region pool risks in a diversified portfolio. Examples
4 include Africa Risk Capacity (ARC), the Caribbean Catastrophe Risk Insurance Facility (CCRIF), and
5 the Pacific Catastrophe Risk Assessment and Financing Initiative (PCRAFI) (Bresch et al. 2017;
6 Iyahan and Syroka 2018). ARC payouts have been used to assist over 2.1 million food insecure
7 people and provide over 900,000 cattle with subsidised feed in the affected countries (Iyahan and
8 Syroka 2018). ARC has also developed the Extreme Climate Facility, which is designed to
9 complement existing bilateral, multilateral and private sources of finance to enable proactive
10 adaptation (Vincent et al. 2018). It provides beneficiaries the opportunity to increase their benefit by
11 reducing exposure to risk through adaptation and risk reduction measures, thus side-stepping “moral
12 hazard” problems sometimes associated with traditional insurance.

13 Governments pay coupon interest when purchasing catastrophe (CAT) bonds from private or
14 corporate investors. In the case of the pre-defined catastrophe, the requirement to pay the coupon
15 interest or repay the principal may be deferred or forgiven (Nguyen and Lindenmeier 2014). CAT
16 bonds are typically short-term instruments (3–5 years) and the payout is triggered once a particular
17 threshold of disaster/damage is passed (Härdle and Cabrera 2010; Campillo et al. 2017; Estrin and
18 Tan 2016; Hermann, A., Kofler, P., Mairhofer 2016; Michel-Kerjan 2011; Roberts 2017). The
19 primary advantage of CAT bonds is their ability to quickly disburse money in the event of a
20 catastrophe (Estrin and Tan 2016). Green bonds, social impact bonds, and resilience bonds are other
21 instruments that can be used to fund land based interventions. However, there are significant barriers
22 for developing country governments to enter into the bond market: lack of familiarity with the
23 instruments; lack of capacity and resources to deal with complex legal arrangements; limited or non-
24 existent data and modelling of disaster exposure; and other political disincentives linked to insurance.
25 For these reasons the utility and application of bonds is currently largely limited to higher-income
26 developing countries (Campillo et al. 2017; Le Quesne 2017).

27 **7.4.7.3. Innovative financing approaches for transition to low carbon economies**

28 Traditional financing mechanisms have not been sufficient and thereby leave a gap in facilitating a
29 rapid transition to a low carbon economy or building resilience (Geddes et al. 2018). More recently
30 there have been developments in more innovative mechanisms including crowdfunding (Lam and
31 Law 2016), often supported by national governments (in the U.K. through regulatory and tax
32 support)(Owen et al. 2018). Crowdfunding has no financial intermediaries and thus low transaction
33 costs, and the projects have a greater degree of independence than bank or institution funding (Miller
34 et al. 2018). Other examples of innovative mechanisms are community shares for local projects, such
35 as renewable energy (Holstenkamp and Kahla 2016), or Corporate Power Purchase Agreements
36 (PPAs) used by companies such as Google and Apple to purchase renewable energy directly or
37 virtually from developers (Miller et al. 2018). Investing companies benefit from avoiding
38 unpredictable price fluctuations as well as increasing their environmental credentials. A second
39 example is auctioned price floors, or subsidies that offer a guaranteed price for future emission
40 reductions, currently being trialled in developing countries, by the World Bank Group, known as the
41 Pilot Auction Facility (PAF) (Bodnar et al. 2018). Price floors can maximise the climate impact per
42 public dollar while incentivising private investment in low-carbon technologies, and ideally would be
43 implemented in conjunction with complementary policies such as carbon pricing.

44 In order for climate finance to be as effective and efficient as possible, cooperation between private,
45 public and third sectors (e.g., NGOs, cooperatives, community groups) is more likely to create an
46 enabling environment for innovation (Owen et al. 2018). While innovative private sector approaches
47 are making significant progress, the existence of a stable policy environment that provides certainty
48 and incentives for long term private investment is critical.

49 **7.4.8. Enabling effective policy instruments – Policy Portfolio Coherence**

50 An enabling environment for policy effectiveness includes: 1) the development of comprehensive
51 policies, strategies and programs (section 7.4); 2) human and financial resources that ensure policies,

1 programs and legislation are translated into action; 3) decision making that draws on evidence
2 generated from functional information systems that make it possible to monitor trends; track and map
3 actions; and assess impact in a manner that is timely and comprehensive (see 7.5); 4) governance
4 coordination mechanisms and partnerships; and 5) a long term perspective in terms of response
5 options, monitoring, and maintenance (see 7.6) (FAO 2017a).

6 A comprehensive consideration of policy portfolios achieves sustainable land and climate
7 management (*medium confidence*) (Mobarak and Rosenzweig 2013; Stavropoulou et al. 2017)
8 (Jeffrey et al. 2017) (Howlett and Rayner 2013) (Aalto et al. 2017; Brander and Keith 2015; Williams
9 and Abatzoglou 2016) (Linnerooth-Bayer and Hochrainer-Stigler 2015) (FAO 2017b; Bierbaum and
10 Cowie 2018). Supporting the study of enabling environments, the study of policy mixes has emerged
11 in the last decade in regards to the mix or set of instruments that interact together and are aimed at
12 achieving policy objectives in a dynamic setting (Reichardt et al. 2015). The study of policy mixes
13 includes studying the ultimate objectives of a policy mix (such as biodiversity (Ring and Schröter-
14 Schlaack 2011)), the interaction of policy instruments within the mix (including climate change
15 mitigation and energy (del Río and Cerdá 2017)) (see Trade-offs and Synergies, 7.5.6), and the
16 dynamic nature of the policy mix (Kern and Howlett 2009)).

17 Studying policy mixes allows for a consideration of policy coherence which is broader than the study
18 of discrete policy instruments in rigidly defined sectors, but entails studying policy in relation to the
19 links and dependencies among problems and issues (FAO 2017b). Consideration of policy coherence
20 is a new approach rejecting simplistic solutions, but acknowledging inherently complex processes
21 involving collective consideration of public and private actors in relation to policy analysis (FAO
22 2017b). A coherent, consistent mix of policy instruments can solve complex policy problems
23 (Howlett and Rayner 2013) as it involves lateral, integrative, and holistic thinking in defining and
24 solving problems (FAO 2017b). Such a consideration of policy coherence is required to achieve
25 sustainable development (FAO 2017b; Bierbaum and Cowie 2018). Considerations of policy
26 coherence potentially addresses three sets of challenges: challenges that exist with assessing multiple
27 hazards and sectors (Aalto et al. 2017; Brander and Keith 2015; Williams and Abatzoglou 2016);
28 challenges in mainstreaming adaptation and risk management into on-going development planning
29 and decision making (Linnerooth-Bayer and Hochrainer-Stigler 2015); challenges in scaling up
30 community and ecosystem based initiatives in countries overly focused on sectors, instead of
31 sustainable use of biodiversity and ecosystem services (Reid 2016). There is a gap in integrated
32 consideration of adaptation, mitigation, climate change policy and development. A study in Indonesia
33 found while internal policy coherence between mitigation and adaptation is increasing, external policy
34 coherence between climate change policy and development objectives is still required (Di Gregorio et
35 al. 2017).

36 There is *medium evidence and high agreement* that a suite of agricultural business risk programs
37 (which would include crop insurance and income stability programs) increase farm financial
38 performance, reduce risk, and also reinforce incentives to adopt stewardship practices (beneficial
39 management practices) improving the environment (Jeffrey et al. 2017). Consideration of the portfolio
40 of instruments responding to climate change and its associated risks, and the interaction of policy
41 instruments, improve agricultural producer livelihoods (Hurlbert 2018b). In relation to hazards, or
42 climate related extremes (7.4.3), the policy mix has been found to be a key determinant of the
43 adaptive capacity of agricultural producers. In relation to drought, the mix of policy instruments
44 including crop insurance, sustainable land management practices, bankruptcy and insolvency, co-
45 management of community in water and disaster planning, and water infrastructure programmes are
46 effective at responding to drought (Hurlbert 2018b; Hurlbert and Mussetta 2016; Hurlbert and Pittman
47 2014; Hurlbert and Montana 2015; Hurlbert 2015a) (Hurlbert and Gupta 2018). Similarly in relation
48 to flood, the mix of policy instruments including flood zone mapping, land use planning, flood zone

1 building restrictions, business and crop insurance, disaster assistance payments, preventative
2 instruments including environmental farm planning (including soil and water management (see
3 Chapter 6)) and farm infrastructure projects, and recovery from debilitating flood losses ultimately
4 through bankruptcy are effective at responding to flood (Hurlbert 2018a)(see 7.6.3 Case Study Flood
5 and Flood Security).

6 In respect of land conservation and management goals, consideration of differing strengths and
7 weakness of instruments is necessary. While direct regulation may secure effective minimum
8 standards of biodiversity conservation and critical ecosystem service provision, economic instruments
9 may achieve reduced compliance costs as costs are borne by policy addressees (Rogge and Reichardt
10 2016). In relation to GHG emissions and climate mitigation a comprehensive mix of instruments
11 targeted at emissions reductions, learning, and research and development is effective (*high*
12 *confidence*) (Fischer and Newell 2008). The policy coherence between climate policy and public
13 finance is critical in ensuring the efficiency, effectiveness and equity of mitigation policy, and
14 ultimately to make stringent mitigation policy more feasible (Siegmeier et al. 2018). Recycling
15 carbon tax revenue to support clean energy technologies can decrease losses from unilateral carbon
16 mitigation targets with complementary technology policies (Corradini et al. 2018).

17 When evaluating a new policy instrument, its design in relation to achieving an environmental goal or
18 solving a land and climate change issue, includes consideration of how the new instrument will
19 interact with existing instruments operating at multiple levels (international, regional, national, sub-
20 national, and local) (Ring and Schröter-Schlaack 2011)(see 7.4.1).

21

22 **7.4.9. Barriers to Implementing Policy Responses**

23 There are barriers to implementing the policy instruments that arise in response to the risks from
24 climate-land interactions. Such barriers to climate action help determine the degree to which society
25 can achieve its sustainable development objectives (Dow et al. 2013; Langholtz et al. 2014; Klein et
26 al. 2015). However, some policies can also be seen as being designed specifically to overcome
27 barriers, while in some cases policies may actually create or strengthen barriers to climate action
28 (Foudi and Erdlenbruch 2012; Linnerooth-Bayer and Hochrainer-Stigler 2015). The concept of
29 barriers to climate action is used here in a sense close to that of “soft limits” to adaptation (Klein, et
30 al. 2014). “Hard limits” by contrast are seen as primarily biophysical. Predicted changes in the key
31 factors of crop growth and productivity—temperature, water, and soil quality— are expected to pose
32 limits to adaptation in ways that affect the world’s population to get enough food in the future (Altieri
33 et al. 2015; Altieri and Nicholls 2017).

34 This section assesses research on barriers specific to policy implementation in adaptation and
35 mitigation respectively, then addresses the cross-cutting issue of inequality as a barrier to climate
36 action, including the particular cases of elite capture and corruption, before assessing how policies on
37 climate and land can be used to overcome barriers.

38 **7.4.9.1. Barriers to Adaptation**

39 There are human, social, economic, and institutional barriers to adaptation to land-climate challenges
40 as described in Tabel 7.4 (*medium evidence, high agreement*). Considerable literature exists around
41 changing behaviours through response options targeting social and cultural barriers (Rosin 2013;
42 Eakin; Marshall et al. 2012) (See Chapter 6 Value chain interventions).

1

Table 7.4 Soft Barriers and Limits to Adaptation

Category	Description	References
Human	Cognitive and behavioural obstacles. Lack of knowledge and information.	(Hornsey et al. 2016; Prokopy et al. 2015) (Wreford et al. 2017)
Social	Undermined participation in decision making and social equity	(Burton et al. 2008) (Laube et al. 2012)
Economic	Market failures and missing markets, transaction costs and political economy, ethical and distributional issues. Perverse incentives. Lack of domestic funds, inability to access international funds	(Chambwera et al. 2014b) (Wreford et al. 2017) (RocheCouste et al. 2015; Baumgart-Getz et al. 2012)
Institutional	Mal-coordination of policies and response options, unclear responsibility of actors and leadership, misuse of power, all reducing social learning. Government failures. Path dependent institutions.	(Oberlack 2017) (Sánchez et al. 2016; Greiner and Gregg 2011)
Technological	Systems of mixed crop and livestock. Polycultures.	(Nalau and Handmer 2015)

2

3 Since AR5 research examining the role of governance, institutions and in particular policy
4 instruments, in creating or overcoming barriers to adaptation to land and climate change in the land
5 use sector is emerging (Foudi and Erdlenbruch 2012; Linnerooth-Bayer and Hochrainer-Stigler 2015).
6 Evidence shows that understanding the local context and targeted approaches are generally most
7 successful (Rauken et al. 2014). Understanding the nature of constraints to adaptation is critical in
8 determining how barriers may be overcome. Formal institutions (rules, laws, policies) and informal
9 institutions (social and cultural norms and shared understandings) can be barriers and enablers of
10 climate adaptation (Jantarasami et al. 2010). Governments play a key role in intervening and
11 confronting existing barriers by changing legislation, adopting policy instruments, providing
12 additional resources, and building institutions and knowledge exchange (Ford and Pearce 2010;
13 Measham et al. 2011; Mozumder et al. 2011; Storbjörk 2010). Understanding institutional barriers is
14 important in addressing barriers (*high confidence*). Institutional barriers may exist due to the path-
15 dependent nature of institutions governing natural resources and public good, bureaucratic structures
16 that undermine horizontal and vertical integration (see 7.6.2), and lack of policy coherence (see 7.4.8).

17 Governments play a key role in intervening and confronting existing barriers by changing legislation,
18 adopting policy instruments, providing additional resources, and building institutions and knowledge
19 exchange (Ford and Pearce 2010; Measham et al. 2011; Mozumder et al. 2011; Storbjörk 2010).
20 Understanding institutional barriers is important in addressing barriers (*high confidence, robust
21 evidence*). Institutional barriers may exist due to the path-dependent nature of institutions governing
22 natural resources and public good, bureaucratic structures that undermine horizontal and vertical
23 integration (see 7.6.2), and lack of policy coherence (see 7.4.8). Governments play a key role in
24 intervening and confronting existing barriers by changing legislation, adopting policy instruments,
25 providing additional resources, and building institutions and knowledge exchange (Ford and Pearce
26 2010; Measham et al. 2011; Mozumder et al. 2011; Storbjörk 2010). Understanding institutional
27 barriers is important in addressing barriers (*high confidence, robust evidence*). Institutional barriers
28 may exist due to the path-dependent nature of institutions governing natural resources and public
29 good, bureaucratic structures that undermine horizontal and vertical integration (see 7.6.2), and lack
30 of policy coherence (see 7.4.8).

7.4.9.2. Barriers to land based climate mitigation

Barriers to land based mitigation relate to full understanding of the permanence of carbon sequestration in soils or terrestrial biomass, the additionality of this storage, its impact on production and production shifts to other regions, measurement and monitoring systems and costs (Smith et al. 2007). Agricultural producers are more willing to expand mitigation measures already employed (including efficient and effective management of fertiliser including manure and slurry) and less favourable to those not employed such as using dietary additives, adopting genetically improved animals, or covering slurry tanks and lagoons (Feliciano et al. 2014). Barriers identified in land based mitigation include physical environmental constraints including lack of information, education, and suitability for size and location of farm. For instance precision agriculture is not viewed as efficient in small scale farming (Feliciano et al. 2014).

Property rights may be a barrier when there is no clear single party land ownership to implement and manage changes (Smith et al. 2007). In forestry, tenure arrangements may not distribute obligations and incentives for carbon sequestration effectively between public management agencies and private agents with forest licenses. Including carbon in tenure and expanding the duration of tenure may provide stronger incentive for tenure holders to manage carbon as well as timber values (Williamson and Nelson 2017). Effective policy will require answers as to the current status of agriculture in regard to GHG emissions, the degree that emissions are to change, the best pathway to achieve the change, and an ability to know when the target level of change is achieved (Smith et al. 2007). Forest governance may not have the structure to advance mitigation and adaptation. Currently top down traditional modes do not have the flexibility or responsiveness to deal with the complex, dynamic, spatially diverse, and uncertain features of climate change (Timberlake and Schultz 2017; Williamson and Nelson 2017).

In respect of forest mitigation, two main institutional barriers have been found to predominate. First forest management institutions do not consider climate change to the degree necessary for enabling effective climate response and do not link adaptation and mitigation; Second, institutional barriers exist if institutions are not forward looking, do not enable collaborative adaptive management, promote flexible approaches that are reversible as new information becomes available, promote learning and allow for diversity of approaches that can be tailored to different local circumstances (Williamson and Nelson 2017).

Land-based climate mitigation through expansions and enhancements in agriculture, forestry and bioenergy has great potential but also poses great risks and its success will therefore require improved land use planning, strong governance frameworks and coherent and consistent policies. “Progressive developments in governance of land and modernisation of agriculture and livestock and effective sustainability frameworks can help realise large parts of the technical bioenergy potential with low associated GHG emissions”(Smith et al. 2014b, p. 97).

7.4.9.3. Inequality

There is *medium evidence and high agreement* that one of the greatest challenges for land based adaptation and sustainable land management is posed by inequalities that influence vulnerability and coping and adaptive capacity - including age, gender, wealth, knowledge, access to resources and power (Kunreuther et al. 2014; IPCC 2012; Olsson et al. 2014). Gender is the dimension of inequality that has been the focus of most research while research demonstrating differential impacts, vulnerability and adaptive capacity based on age, ethnicity and indigeneity is less well developed (Olsson et al. 2015a). Cross-Chapter Box 11 sets out both the contribution of gender relations to differential vulnerability and available policy instruments for greater gender inclusivity.

One response to the vulnerability of poor people and other categories differentially affected is effective and reliable social safety nets (Jones and Hiller 2017). Social protection coverage is low across the world and informal support systems continue to be the key means of protection for a

1 majority of the rural poor and vulnerable (Stavropoulou et al. 2017)(See 7.4.2). However, there is a
2 gap in knowledge in understanding both positive and negative synergies between formal and informal
3 systems of social protection and how local support institutions might be used to implement more
4 formal forms of social protection (Stavropoulou et al. 2017).

5 **7.4.9.4. Corruption and elite capture**

6 Inequalities of wealth and power can allow processes of corruption and elite capture which can affect
7 both adaptation and mitigation actions, at levels from the local to the global, that in turn risk creating
8 inequitable or unjust outcomes (Sovacool 2018) (*limited evidence, medium agreement*). This includes
9 risks of corruption in REDD+ processes (Sheng et al. 2016; Williams and Dupuy 2018) and of
10 corruption or elite capture in broader forest governance (Sundström 2016; Persha and Andersson
11 2014), as well as elite capture of benefits from planned adaptation at a local level (Sovacool 2018).

12 Peer-reviewed empirical studies that focus on corruption in climate finance and climate interventions,
13 particularly at a local level, are rare, due in part to the obvious difficulties of researching illegal and
14 clandestine activity (Fadairo et al. 2017). At the country level, historical levels of corruption are
15 shown to affect current climate policies and global cooperation (Fredriksson and Neumayer 2016).
16 Brown (2010) sees three likely inlets of corruption into REDD: in the setting of forest baselines, the
17 reconciliation of project and natural credits, and the implementation of control of illegal logging. The
18 transnational and north-south dimensions of corruption are highlighted by debates on which US
19 legislative instruments (e.g., the Lacey Act, the Foreign Corrupt Practices Act) could be used to
20 prosecute the northern corporations that are involved in illegal logging (Gordon 2016; Waite 2011).

21 Fadairo et al. (2017) carried out a structured survey of perceptions of households in forest-edge
22 communities served by REDD+, as well as those of local officials, in south eastern Nigeria. They
23 report high rates of agreement that allocation of carbon rights is opaque and uncertain, distribution of
24 benefits is untimely, uncertain and unpredictable, and the REDD+ decision-making process is
25 vulnerable to political interference that benefits powerful individuals. Only 35% of respondents had
26 an overall perception of transparency in REDD+ process as “good”. Of eight institutional processes or
27 facilities previously identified by the Government of Nigeria and international agencies as indicators
28 of commitment to transparent and equitable governance, only three were evident in the local REDD+
29 office as “very functional” or “fairly functional”.

30 At the local level, the risks of corruption and elite capture of the benefits of climate action are high in
31 decentralised regimes (Persha and Andersson 2014). (Rahman 2018) discusses elicitation of bribes
32 (by local-level government staff) and extortion (by criminals) to allow poor rural people to gather
33 forest products. The results are a general undermining of households’ adaptive capacity and perverse
34 incentives to over-exploit forests once bribes have been paid, leading to over-extraction and
35 biodiversity loss. Where there are pre-existing inequalities and conflict, participation processes need
36 careful management and firm external agency to achieve genuine transformation and avoid elite
37 capture (Rigon 2014). An illustration of the range of types of elite capture is given by Sovacool
38 (2018) for adaptation initiatives including coastal afforestation, combining document review and key
39 informant interviews in Bangladesh, with an analytical approach from political ecology. Four
40 processes are discussed: enclosure, including land grabbing and preventing the poor establishing new
41 land rights; exclusion of the poor from decision-making over adaptation; encroachment on the
42 resources of the poor by new adaptation infrastructure; and entrenchment of community
43 disempowerment through patronage. The article notes that observing these processes does not imply
44 they are always present, nor that adaptation efforts should be abandoned.

45 **7.4.9.5. Overcoming Barriers**

46 Policy instruments that strengthen agricultural producer assets or capitals reduce vulnerability and
47 overcome barriers to adaptation (Hurlbert 2018b, 2015b). Additional factors like formal education
48 and knowledge of traditional farming systems, secure tenure rights, access to electricity and social

1 institutions in rice-farming areas of Bangladesh have played a positive role in reducing adaptation
2 barriers (Alam 2015). A review of over 168 publications over 15 years about adaptation of water
3 resources for irrigation in Europe found the highest potential for action is in improving adaptive
4 capacity and responding to changes in water demands, in conjunction with alterations in current water
5 policy, farm extension training, and viable financial instruments (Iglesias and Garrote 2015). Research
6 on the Great Barrier Reef, the Olifants River in Southern Africa, and fisheries in Europe, North
7 America, and the Antarctic Ocean, suggests the leading factors in harnessing the adaptive capacity of
8 ecosystems is to reduce human stressors by enabling actors to collaborate across diverse interests,
9 institutional settings, and sectors (Biggs et al. 2017; Schultz et al. 2015; Johnson and Becker 2015).
10 Fostering equity and participation are correlated with the efficacy of local adaptation to secure food
11 and livelihood security (Laube et al. 2012). In this chapter, the literature surrounding appropriate
12 policy instruments, decision making, and governance practices to overcome limits and barriers to
13 adaptation is proposed.

14 Incremental adaptation consists of actions where the central aim is to maintain the essence and
15 integrity of a system or process at a given site whereas transformational adaptation is adaptation that
16 changes the fundamental attributes of a system in response to climate and its effects; the former is
17 characterised as doing different things and the latter, doing things differently (Noble et al. 2014).
18 Transformational adaptation is necessary in situations where there are hard limits to adaptation or it is
19 desirable to address deficiencies in sustainability, adaptation, inclusive development and social equity
20 (Kates et al. 2012; Mapfumo et al. 2016). In other situations, incremental changes may be sufficient
21 (Hadarits et al. 2017).

22

23 **Cross-chapter Box 11: Gender in inclusive approaches to climate** 24 **change, land, and sustainable development**

25

26 Margot Hurlbert (Canada), Brigitte Baptiste (Colombia), Amber Fletcher (Canada), Marta Guadalupe
27 Rivera Ferre (Spain), Darshini Mahadevia (India), Katharine Vincent (United Kingdom)

28

29 Gender is a key axis of social inequality that intersects with other systems of power and
30 marginalisation—including “race”, culture, class/socioeconomic status, location, sexuality, and age—
31 to cause unequal experiences of climate change vulnerability and adaptive capacity. However, “policy
32 frameworks and strong institutions that align development, equity objectives, and climate have the
33 potential to deliver ‘triple-wins’” (Roy et al. 2018), including enhanced gender equality. Gender in
34 relation to this report is introduced in Chapter 1, referred to as a leverage point in women’s
35 participation in decisions relating to land desertification (3.6.3), land degradation (4.1.6), food
36 security (5.2.5.1), and enabling land and climate response options (6.1.2.2).

37

38 Focusing on ‘gender’ as a relational and contextual construct can help avoid homogenising “women”
39 as a uniformly and consistently vulnerable category (Arora-Jonsson 2011; Mersha and Van Laerhoven
40 2016; Ravera et al. 2016). There is *high agreement* that using a framework of intersectionality to
41 integrate gender into climate change research helps to recognise overlapping and interconnected
42 systems of power (Djoudi et al. 2016; Fletcher 2018; Kaijser and Kronsell 2014; Moosa and Tuana
43 2014; Thompson-Hall et al. 2016), which create particular inequitable experiences of climate change
44 vulnerability and adaptation. Through this framework, both commonalities and differences may be
45 found between the experiences of rural and urban women, or between women in high-income and
46 low-income countries, for example.

47

48 In rural areas, women generally experience greater vulnerability than men, albeit through different
49 pathways (Djoudi et al., 2016; Goh, 2012; Jost et al., 2016; Kakota, Nyariki, Mkwambisi, & Kogi-

1 Makau, 2011). In masculinised agricultural settings of Australia and Canada, for example, climate
2 adaptation can increase women's work on- and off-farm, but without increasing recognition for
3 women's undervalued contributions (Alston et al. 2018a; Fletcher and Knuttila 2016). A study in
4 rural Ethiopia found that male-headed households had access to a wider set of adaptation measures
5 than female-headed households (Mersha and Van Laerhoven 2016).

6
7 Due to engrained patriarchal social structures and gendered ideologies, women may face multiple
8 barriers to participation and decision-making in land-based adaptation and mitigation actions in
9 response to climate change (*high confidence*) (Alkire et al. 2013a; Quisumbing et al. 2014). These
10 barriers include: (i) disproportionate responsibility for unpaid domestic work, including care-giving
11 activities (Beuchelt and Badstue 2013) and provision of water and firewood (UNEP, 2016); (ii) risk
12 of violence in both public and private spheres, which restricts women's mobility for capacity-building
13 activities and productive work outside the home (Day et al., 2005; Jost et al., 2016; UNEP, 2016); (iii)
14 less access to credit and financing (Jost et al. 2016); (iv) lack of organisational social capital, which
15 may help in accessing credit (Carroll et al. 2012); (v) lack of ownership of productive assets and
16 resources (Kristjanson et al., 2014; Meinzen-Dick et al., 2010), including land. Constraints to land
17 access include not only state policies, but also customary laws (Bayisenge 2018) based on customary
18 norms and religion that determine women's rights (Namubiru-Mwaura 2014a).

19
20 Differential vulnerability to climate change is related to inequality in rights-based resource access,
21 established through formal and informal tenure systems. In only 37% of 161 developing and
22 developed countries do men and women have equal rights to use and control land, and in 59%
23 customary, traditional, and religious practices discriminate against women (OECD 2014), even if the
24 law formally grants equal rights. Women play a significant role in agriculture, food security and rural
25 economies globally, forming 43% of the agricultural labour force in developing countries (FAO,
26 IFAD, UNICEF, & WHO, 2018, p. 102), ranging from 25 % in Latin America (FAO, 2017, pp. 89) to
27 nearly 50% in Eastern Asia and Central and South Europe (FAO, 2017, p. 88) and 47% in sub-
28 Saharan Africa (FAO, 2017, pp. 88). Further, the share of women in agricultural employment has
29 been growing in all developing regions except East Asia and Southeast Asia (FAO, 2017, p. 88). At
30 the same time, women constitute less than 5% of landholders (with legal rights and/or use-rights
31 (Doss et al. 2018a) in North Africa and West Asia, about 15% in sub-Saharan Africa, 12% in
32 Southern and Southeastern Asia, 18% in Latin America and Caribbean (FAO 2011b, p. 25), 10% in
33 Bangladesh, 4% in Nigeria (FAO 2015c). Patriarchal structures and gender roles can also affect
34 women's control over land in developed countries (Carter 2017; Alston et al. 2018b). Thus,
35 longstanding gender inequality in land rights, security of tenure, and decision-making may constrict
36 women's adaptation options (Smucker and Wangui 2016).

37
38 Adaptation options related to land and climate (see Chapter 6) may produce environment and
39 development trade-offs as well as social conflicts (Hunsberger et al. 2017) and changes with gendered
40 implications. Women's strong presence in agriculture provides opportunity to bring gender
41 dimensions into climate change adaptation, particularly regarding food security (Glemarec 2017; Jost
42 et al. 2016; Doss et al. 2018b). Some studies point to a potentially emancipatory role played by
43 adaptation interventions and strategies, albeit with some limitations depending on context. For
44 example, in developing contexts, male out-migration may cause women in socially disadvantaged
45 groups to engage in new livelihood activities, thus challenging gendered roles (Djoudi and Brockhaus
46 2011; Alston 2006). Collective action and agency of women in farming households, including
47 widows, have led to prevention of crop failure, reduced workload, increased nutritional intake,
48 increased sustainable water management, diversified and increased income and improved strategic
49 planning (Andersson and Gabrielsson 2012). Women's waged labour can help stabilise income from
50 more land- and climate-dependent activities such as agriculture, hunting, or fishing (Alston et al.,
51 2018; Ford & Goldhar, 2012). However, in developed contexts like Australia, women's participation
52 in off-farm employment may exacerbate existing masculinisation of agriculture (Clarke and Alston
53 2017).

54
55 Literature suggests that land-based mitigation measures may lead to land alienation either through

1 market or appropriation (acquisition) by the government, interfere with traditional livelihoods in rural
2 areas, and lead to decline in women's livelihoods (Hunsberger et al. 2017). If land alienation is not
3 prevented, existing inequities and social exclusions may be reinforced (*medium agreement*)
4 (Mustalahti and Rakotonarivo 2014; Chomba et al. 2016; Poudyal et al. 2016). These activities also
5 can lead to land grabs, which remain a focal point for research and local activism (Borras Jr. et al.
6 2011; White et al. 2012; Lahiff 2015). Cumulative effects of land-based mitigation measures may put
7 families at risk of poverty. In certain contexts, they lead to increased conflicts. In conflict situations,
8 women are at risk of personal violence, including sexual violence (UNEP, 2016).

9 10 **Policy instruments for gender inclusive approaches to climate change, land, and sustainable** 11 **development**

12
13 Integrating, or mainstreaming, gender into land and climate change policy requires assessments of
14 gender-differentiated needs and priorities, selection of appropriate policy instruments to address
15 barriers to women's sustainable land management, and selection of gender indicators for monitoring
16 and assessment of policy (*medium confidence*) (Huyer et al. 2015a; Alston 2014). Important sex-
17 disaggregated data can be obtained at multiple levels, including the intra-household level (Seager
18 2014; Doss et al. 2018b), village- and plot-level information (Theriault et al. 2017a), and through
19 national surveys (Agarwal 2018a; Doss et al. 2015a). Gender-disaggregated data provides a basis for
20 selecting, monitoring and reassessing policy instruments that account for gender differentiated land
21 and climate change needs (*medium confidence*) (Rao 2017a; Arora-Jonsson 2014; Theriault et al.
22 2017b) (Doss et al. 2018b). While macro-level data can reveal ongoing gender trends in SLM,
23 contextual data are important for revealing intersectional aspects, such as the difference made by
24 family relations, socioeconomic status, or cultural practices about land use and control (Rao 2017a;
25 Arora-Jonsson 2014; Theriault et al. 2017b), as well as on security of land holding (Doss et al.
26 2018b). Indices such as the Women's Empowerment in Agriculture Index (Alkire et al. 2013b) may
27 provide useful guidelines for quantitative data collection on gender and SLM, while qualitative
28 studies can reveal the nature of agency and whether policies are likely to be accepted, or not, in the
29 context of local structures, meanings, and social relations (Rao 2017b).

30
31 Women's economic empowerment, decision-making power and voice is a necessity in SLM decisions
32 (Mello and Schmink 2017a; Theriault et al. 2017b). Policies that address barriers include: gender
33 considerations as qualifying criteria for funding programs or access to financing for initiatives;
34 government transfers to women under the auspices of anti-poverty programs; spending on health and
35 education; and subsidised credit for women (*medium confidence*) (Jagger and Pender 2006; Van
36 Koppen et al. 2013a; Theriault et al. 2017b; Agarwal 2018b). Training and extension for women to
37 facilitate sustainable practices is also important (Mello and Schmink 2017b; Theriault et al. 2017b).
38 Such training could be built into existing programs or structures, such as collective microenterprise
39 (Mello and Schmink 2017b). Huyer et al. (2015) suggest that information provision (e.g., information
40 about SLM) could be effectively dispersed through women's community-based organisations,
41 although not in such a way that it overwhelms these organisations or supersedes their existing
42 missions. SLM programs could also benefit from intentionally engaging men in gender-equality
43 training and efforts (Fletcher 2017), thus recognising the relationality of gender. Recognition of the
44 household level, including men's roles and power relations, can help avoid the de-contextualised and
45 individualistic portrayal of women as purely instrumental actors (Rao 2017b).

46
47 Technology, policy, and programs that exacerbate women's workloads or reinforce gender stereotypes
48 (MacGregor 2010; Huyer et al. 2015b), or which fail to recognise and value the contributions women
49 already make (Doss et al. 2018b), may further marginalise women. Accordingly, some studies have
50 described technological and labour interventions that can enhance sustainability while also decreasing
51 women's workloads; for example, Vent et al. (2017) described the system of rice intensification as
52 one such intervention. REDD+ initiatives need to be aligned with the SDGs to achieve
53 complementary synergies with gender dimensions.

54
55 Secure land title and/or land access/control for women increases sustainable land management by

1 increasing women's conservation efforts, increasing their productive and environmentally-beneficial
2 agricultural investments, such as willingness to engage in tree planting and sustainable soil
3 management (*high confidence*) as well as improving cash incomes (Higgins et al. 2018; Agarwal
4 2010; Namubiru-Mwaura 2014b; Doss et al. 2015b; Van Koppen et al. 2013b; Theriault et al. 2017b;
5 Jagger and Pender 2006). According FAO (2011b, p. 5), if women had the same access to productive
6 resources as men, the number of hungry people in the world could be reduced by 12-17%. Policies
7 promoting secure land title include legal reforms at multiple levels, including national laws on land
8 ownership, legal education, and legal aid for women on land ownership and access (Argawal 2018).
9 Policies to increase women's access to land could occur through three main avenues of land
10 acquisition: inheritance/family (Theriault et al. 2017b), state policy, and the market (Agarwal 2018).
11 Rao (2017) recommends framing land rights as entitlements rather than as instrumental means to
12 sustainability. This reframing may address persistent, pervasive gender inequalities (FAO 2015d).
13
14
15

16 **7.5. Decision-making for Climate Change and Land**

17 The risks posed by climate change generate considerable uncertainty and complexity for decision-
18 makers responsible for land use decisions (*robust evidence, high agreement*). Decision-makers
19 balance climate ambitions, encapsulated in the NDCs, with other SDGs, which will differ
20 considerably across different regions, sociocultural conditions and economic levels (Griggs et al.
21 2014). The interactions across SDGs also factor into decision-making processes (Nilsson et al.
22 2016b). The challenge is particularly acute in Least Developed Countries where a large share of the
23 population is vulnerable to climate change. Matching the structure of decision-making processes to
24 local needs while connecting to national strategies and international regimes is challenging (Nilsson
25 and Persson 2012). This section explores methods of decision-making to address the risks and inter-
26 linkages outlined in previous sections. As a result, this section outlines policy inter-linkages with
27 SDGs and NDCs, trade-offs and synergies in specific measures, possible challenges as well as
28 opportunities going forward.

29 Even in cases where uncertainty exists, there is *medium evidence and high agreement* in the literature
30 that it need not present a barrier to taking action, and there are growing methodological developments
31 and empirical applications to support decision-making. Progress has been made in identifying key
32 source of uncertainty and addressing them (Farber 2015; Lawrence et al. 2018; Bloemen et al. 2018).
33 Many of these approaches involve principles of robustness, diversity, flexibility, learning, or choice
34 editing (see 7.5.2).

35 Since the Fifth Assessment Report Chapter on Decision-making (Jones et al. 2014) considerable
36 advances have been made in decision making under uncertainty, both conceptually and in economics
37 (see 7.5.2), and in the social/qualitative research areas (see 7.5.3 and 7.5.4). In the land sector, the
38 degree of uncertainty varies and is particularly challenging for climate change adaptation decisions
39 (Hallegatte 2009; Wilby and Dessai 2010). Some types of agricultural production decisions can be
40 made in short time-frames as changes are observed, and will provide benefits in the current time
41 period (Dittrich et al. 2017).

42 **7.5.1. Formal and Informal decision-making**

43 Informal decision making facilitated by open platforms can solve problems in land and resource
44 management by allowing evolution and adaptation, and incorporation of local knowledge (*medium*
45 *confidence* (Malogdos and Yujuico 2015a; Vandersypen et al. 2007). Formal centers of decision
46 making are those that follow fixed procedures (written down in statutes or moulded in an organisation

1 backed by the legal system) and structures (Onibon et al. 1999). Informal centers of decision making
2 are those following customary norms and habits based on conventions (Onibon et al. 1999) where
3 problems are ill-structured, complex problems (Waddock 2013).

4 **7.5.1.1. Formal Decision Making**

5 Formal decision making processes can occur at all levels including the global, regional, national and
6 sub-national levels (see 7.4.1). Formal decision support tools can be used, for example, by farmers, to
7 answer “what-if” questions as to how to respond to the effects of changing climate on soils, rainfall
8 and other conditions (Wenkel et al. 2013).

9 Optimal formal decision-making is based on realistic behaviour of actors, important in land-climate
10 systems, assessed through participatory approaches, stakeholder consultations and by incorporating
11 results from empirical analyses. Mathematical simulations and games (Lamarque et al. 2013),
12 behavioural models in land-based sectors (Brown et al. 2017), agent-based models (ABMs) and
13 micro-simulations are examples useful to decision-makers (Bishop et al. 2013). These decision
14 making tools are expanded on in 7.5.2.

15 There are different ways to incorporate local knowledge, informal institutions and other contextual
16 characteristics that capture non-deterministic elements, as well as social and cultural beliefs and
17 systems more generally, into formal decision making (see 7.6.4) (*medium evidence, medium*
18 *agreement*). Classic scientific methodologies now include participatory and interdisciplinary methods
19 and approaches (Jones et al. 2014). Consequently, this broader range of approaches may very well
20 capture informal and indigenous knowledge improving the participation of indigenous peoples in
21 decision-making processes and thereby promote their rights to self-determination (Malogdos and
22 Yujuico 2015b) (see Cross-Chapter Box 13: Indigenous and Local Knowledge in this chapter).

23 **7.5.1.2. Informal Decision Making**

24 Informal institutions have contributed to sustainable resources management (common pool resources)
25 through creating a suitable environment for decision-making. The role of informal institutions and
26 decision making can be particularly relevant for land use decisions and practices in rural areas in the
27 global south and north (Huisheng 2015). Understanding informal institutions is crucial for adapting
28 to climate change, advancing technological adaptation measures achieving comprehensive disaster
29 management and advancing collective decision making (Karim and Thiel 2017). Informal institutions
30 have been found to be a crucial entry point in dealing with vulnerability of communities and
31 exclusionary tendencies impacting marginalised and vulnerable people (Mubaya and Mafongoya
32 2017).

33 Many studies underline the role of local/informal traditional institutions in the management of natural
34 resources in different parts of the world (Yami et al. 2009; Zoogah et al. 2015; Bratton 2007; Mowo et
35 al. 2013; Grzymala-Busse 2010). Traditional systems include: traditional silvo-pastoral management
36 (Iran), management of rangeland resources (South Africa), natural resource management (Ethiopia,
37 Tanzania, Bangladesh) communal grazing land management (Ethiopia) and management of conflict
38 over natural resources (Siddig et al. 2007; Yami et al. 2011; Valipour et al. 2014; Bennett 2013;
39 Mowo et al. 2013).

40 Formal-informal institutional interaction could take different shapes such as: complementary,
41 accommodating, competing, and substitutive. There are many examples when formal institutions
42 might obstruct, change, and hinder informal institutions (Rahman et al. 2014; Helmke and Levitsky
43 2004; Bennett 2013) (Osei-Tutu et al. 2014). Similarly, informal institutions can replace, undermine,
44 and reinforce formal institutions (Grzymala-Busse 2010). In the absence of formal institutions,
45 informal institutions gain importance requiring focus in relation to natural resources management and

1 rights protection (Estrin and Prevezer 2011; Helmke and Levitsky 2004; Kangalawe.R.Y.M, Noe.C,
2 Tungaraza.F.S.K 2014; Sauerwald and Peng 2013; Zoogah et al. 2015).

3 Community forestry comprises 22% of forests in tropical countries in contrast to large-scale industrial
4 forestry (Hajjar et al. 2013) and is managed with informal institutions ensuring a sustainable flow of
5 forest products and income utilising traditional ecological knowledge to determine access to resources
6 (Singh et al. 2018). Policies that create an open platform for local debates and allow actors their own
7 active formulation of rules strengthen informal institutions. Case studies in Zambia, Mali, Indonesia
8 and Bolivia confirm that enabling factors for advancing the local ownership of resources and crafting
9 durability of informal rules require recognition in laws, regulations and policies of the state (Haller et
10 al. 2016).

11 **7.5.2. Decision Making, Timing, Risk, and Uncertainty**

12 This section assesses decision making literature concluding advances in methods have been made in
13 the face of conceptual risk literature and together with a synthesis of empirical evidence, near term
14 decisions have significant impact on costs.

15 **7.5.2.1. Problem Structuring**

16 Structured decision making occurs when there is scientific knowledge about cause and effect, little
17 uncertainty, and agreement exists on values and norms relating to an issue (Hurlbert and Gupta 2016).
18 This decision space is situated within the “known” space where cause and effect is understood and
19 predictable (although uncertainty is not quite zero) (French 2015). Figure 7.5 displays the structured
20 problem area in the bottom left corner corresponding with the ‘known’ decision making space.
21 Decision making surrounding quantified risk assessment and risk management (7.4.3.1) occurs within
22 this decision making space. Examples in the land and climate area include cost benefit analysis
23 surrounding implementation of irrigation projects (Batie 2008) or adopting soil erosion practices by
24 agricultural producers based on anticipated profit (Hurlbert 2018b). Comprehensive risk management
25 also occupies this decision space (Papathoma-Köhle et al. 2016), encompassing risk assessment,
26 reduction, transfer, retention, emergency preparedness and response, and disaster recovery by
27 combining quantified proactive and reactive approaches (Fra.Paleo 2015) (see 7.4.3).

28 A moderately structured decision space is characterised as one where there is either some
29 disagreement on norms, principles, ends and goals in defining a future state or there is some
30 uncertainty surrounding land and climate including land use, observations of land use changes, early
31 warning and decision support systems, model structures, parameterisations, inputs, or from unknown
32 futures informing integrated assessment models and scenarios (see Chapter 1, 1.2.2 and Cross chapter
33 Box 1 on Scenarios). Environmental decision making often takes place in this space where there is
34 limited information and ability to process it, and individual stakeholders make different decisions on
35 the best future course of action (Waas et al. 2014) (*medium confidence*) (Hurlbert and Gupta 2016,
36 2015; Hurlbert 2018b). Figure 7.5 displays the moderately structured problem space characterised by
37 disagreement surrounding norms on the top left hand side. This corresponds with the complex
38 decision making space, the realm of social sciences and qualitative knowledge, where cause and effect
39 is difficult to relate with any confidence (French 2013).

40 The moderately structured decision space characterised by uncertainty surrounding land and climate
41 on the bottom right hand side of Figure 7.5 as well and corresponds to the knowable decision making
42 space, where the realm of scientific inquiry investigates cause and effects. Here there is sufficient
43 understanding to build models, but not enough understanding to define all parameters (French 2015).

44 The top right hand corner of Figure 7.5 corresponds to the ‘unstructured’ problem or chaotic space
45 where patterns and relationships are difficult to discern and unknown unknowns reside (French 2013).
46 It is in the complex but knowable space, the structured and moderately structured space, that decision
47 making under uncertainty occurs.

7.5.2.2. Decision Making Tools

Decisions can still be made despite uncertainty (*medium confidence*), and a wide range of possible approaches are emerging to support decision-making under uncertainty (Jones et al. 2014), applied both to adaptation and mitigation decisions.

Traditional approaches for economic appraisal, including cost benefit analysis and cost effectiveness analysis referred to in 7.5.2.1 do not handle or address uncertainty well (Hallegatte 2009) (Farber 2015) and favour decisions with short term benefits (see Cross-Chapter Box 10: Economic Dimensions in this chapter). Alternative economic decision making approaches aim to better incorporate uncertainty while still delivering adaptation goals, by selecting projects that meet their purpose across a variety of plausible futures (Hallegatte et al. 2012); so-called ‘robust’ decision-making approaches. These are designed to be less sensitive to uncertainty about the future (Lempert and Schlesinger 2000).

Much of the research for adaptation to climate change has focused around three main economic approaches: Real Options Analysis, Portfolio Analysis, and Robust Decision-Making. Real Options Analysis develops flexible strategies that can be adjusted when additional climate information becomes available. It is most appropriate for large irreversible investment decisions. Applications to climate adaptation are growing quickly, with most studies addressing flood risk and sea-level rise (Gersonius et al. 2013; Woodward et al. 2014; Dan 2016), but studies in land use decisions are also emerging, including identifying the optimal time to switch land use in a changing climate (Sanderson et al. 2016) and water storage (Sturm et al. 2017; Kim et al. 2017). Portfolio analysis aims to reduce risk by diversification, by planting multiple species rather than only one, in forestry (Knoke et al. 2017) or crops (Ben-Ari and Makowski 2016), for example, or in multiple locations. There may be a trade-off between robustness to variability and optimality (Yousefpour and Hanewinkel 2016; Ben-Ari and Makowski 2016); but this type of analysis can help identify and quantify trade-offs. Robust Decision Making identifies how different strategies perform under many climate outcomes, also potentially trading off optimality for resilience (Lempert 2013).

Multi-criteria decision making continues to be an important tool in the land-use sector, with the capacity to simultaneously consider multiple goals across different domains (e.g., economic, environmental, social) (Bausch et al. 2014; Alrø et al. 2016), and is thus useful as a mitigation as well as an adaptation tool. Life-cycle assessment (LCA) can also be used to evaluate emissions across a system (for example in livestock production (McClelland et al. 2018)) and identify areas to prioritise for reductions. Bottom-up Marginal Abatement Cost Curves calculate the most cost-effective cumulative potential for mitigation across different options (Eory et al. 2018).

In the climate adaptation literature, these tools may be used in adaptive management (see 7.5.4), using a monitoring, research, evaluation and learning process (cycle) to improve future management strategies (Tompkins and Adger 2004). More recently these techniques have been advanced with iterative risk management (IPCC 2014a) (see 7.4.1, 7.4.7), adaptation pathways (Downing 2012), and dynamic adaptation pathways (Haasnoot et al. 2013) (see 7.6.3). Decision making tools can be selected and adapted to fit the specific land and climate problem and decision making space. For instance, dynamic adaptation pathways processes (Haasnoot et al. 2013; Wise et al. 2014) identify and sequence potential actions based on alternative potential futures and are situated within the complex, unstructured space (see Figure 7.5). Decisions are made based on trigger points, linked to indicators and scenarios, or changing performance over time (Kwakkel et al. 2016). A key characteristic of these pathways is rather than making irreversible decisions now, decisions evolve over time, accounting for learning (see 7.6.4), knowledge, and values. Combining Dynamic Adaptive Pathways and a form of Real Options Analysis with Multi Criteria Decision Analysis has enabled changing risk over time to be included in assessment of adaptation options through a participatory learning process in New Zealand (Lawrence et al. 2019).

1 Scenario analysis is also situated within the complex, unstructured space (although unlike adaptation
2 pathways, it does not allow for changes in pathway over time) and is important for identifying
3 technology and policy instruments to ensure spatial-temporal coherence of land use allocation
4 simulations with scenario storylines (Brown and Castellazzi 2014) and identifying technology and
5 policy instruments for mitigation of land degradation (Fleskens et al. 2014).

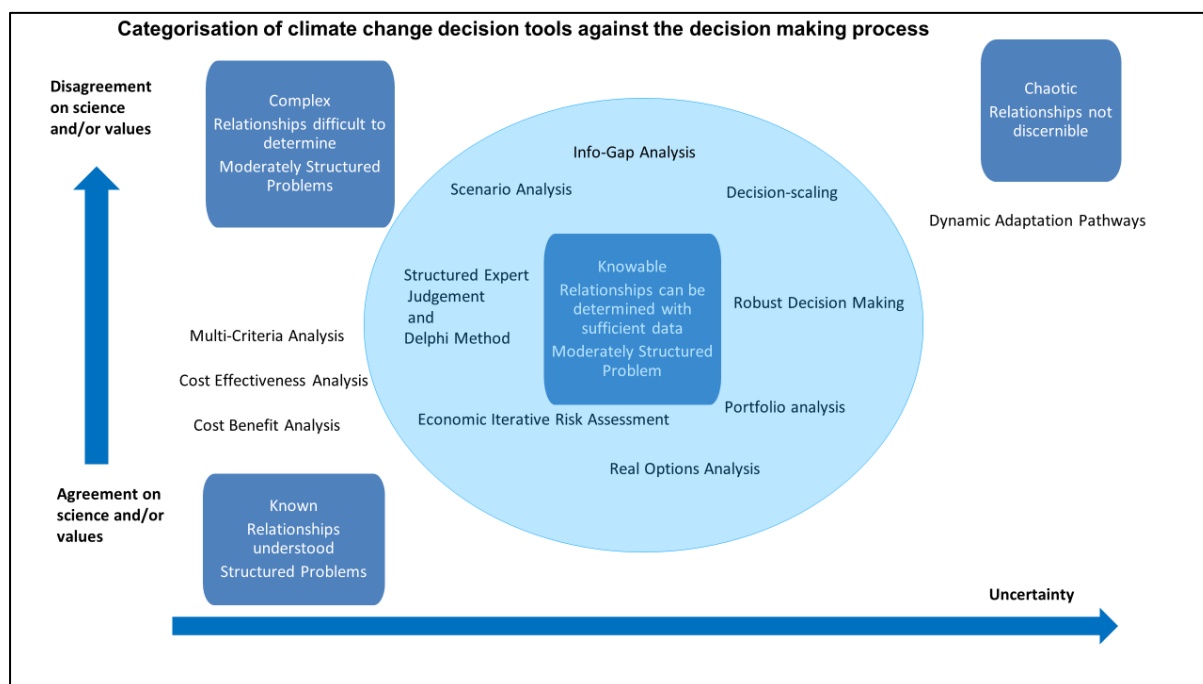

6 While economics is usually based on the idea of a self-interested, rational agent, more recently
7 insights from psychology are being used to understand and explain human behaviour in the field of
8 behavioural economics (Shogren and Taylor 2008; Kesternich et al. 2017), illustrating how a range of
9 cognitive factors and biases can affect choices (Valatin et al. 2016). These insights can be critical in
10 supporting decision-making that will lead to more desirable outcomes relating to land and climate
11 change. One example of this is ‘policy nudges’ (Thaler and Sunstein 2008) which can ‘shift choices
12 in socially desirable directions’ (Valatin et al. 2016). Tools can include framing tools, binding pre-
13 commitments, default settings, channel factors, or broad choice bracketing (Wilson et al. 2016).
14 Although relatively few empirical examples exist in the land sector, there is evidence that nudges
15 could be applied successfully, for example in woodland creation (Valatin et al. 2016) and agri-
16 environmental schemes (Kuhfuss et al. 2016) (*Medium certainty, low evidence*). Consumers can be
17 ‘nudged’ to consume less meat (Rozin et al. 2011) or to waste food less (Kallbekken and Sælen 2013).

18 Programmes supporting and facilitating desired practices can have success at changing behaviour,
19 particularly if they are co-designed by the end-users (farmers, foresters, land-users) (*medium*
20 *evidence, high agreement*). Programmes that focus on demonstration or trials of different adaptation
21 and mitigation measures, and facilitate interaction between farmers, industry specialists are perceived
22 as being successful (Wreford et al. 2017; Hurlbert 2015b) but systematic evaluations of their success
23 at changing behaviour are limited (Knook et al. 2018).

24 Different approaches to decision making are appropriate in different contexts. Dittrich et al. (2017)
25 provide a guide to the appropriate application in different contexts for adaptation in the livestock
26 sector in developed countries. While considerable advances have been made in the theoretical
27 approaches, a number of challenges arise when applying these in practice, and partly relate to the
28 necessity of assigning probabilities to climate projects, and the complexity of the approaches being a
29 prohibitive factor beyond academic exercises. Formalised expert judgement can improve how
30 uncertainty is characterised (Kunreuther et al. 2014) and these methods have been improved utilising
31 Bayesian belief networks to synthesise expert judgements and include fault trees and reliability block
32 diagrams to overcome standard reliability techniques (Sigurdsson et al. 2001) as well as mechanisms
33 incorporating transparency (Ashcroft et al. 2016).

34 It may also be beneficial to combine decision making approaches with the precautionary principle, or
35 the idea that lack of scientific certainty is not to postpone action when faced with serious threats or
36 irreversible damage to the environment (Farber 2015). The precautionary principle requires cost
37 effective measures to address serious but uncertain risks (Farber 2015). It supports a rights based
38 policy instrument choice as consideration is whether actions or inactions harm others moving beyond
39 traditional risk management policy considerations that surround net benefits (Etkin et al. 2012).
40 Farber, (2015) concludes the principle has been successfully applied in relation to endangered species
41 and situations where climate change is a serious enough problem to justify some response. There is
42 *medium confidence* that combining the precautionary principle with integrated assessment models,
43 risk management, and cost benefit analysis in an integrated, holistic manner, together would be a good
44 combination of decision making tools supporting sustainable development (Farber 2015; Etkin et al.
45 2012).

Figure 7.5 Structural and Uncertain Decision Making

5

7.5.2.3. Cost and timing of action

The Cross-Chapter Box 10 on Economics Dimensions deals with the costs and timing of action. In terms of policies, not only is timing important, but the type of intervention itself can influence returns (*high evidence, high agreement*). Policy packages that make people more resilient - expanding financial inclusion, disaster risk and health insurance, social protection and adaptive safety nets, contingent finance and reserve funds, and universal access to early warning systems (see 7.4.1, 7.6.3) – could save USD 100 billion a year, if implemented globally (Hallegatte et al. 2017). In Ethiopia, Kenya and Somalia, every 1 USD spent on safety net/resilience programming results in net benefits of between USD 2.3 and 3.3 (Venton 2018). Investing in resilience building activities, which increase household income by USD 365 to 450 per year in these countries, is more cost effective than providing ongoing humanitarian assistance.

There is a need to further examine returns on investment for land-based adaptation measures, both in the short and long term. Other outstanding questions include identifying specific triggers for early response. Food insecurity, for example, can occur due to a mixture of market and environmental factors (changes in food prices, animal or crop prices, rainfall patterns) (Venton 2018). The efficacy of different triggers, intervention times and modes of funding are currently being evaluated (see for example forecast based finance study (Alverson and Zommers 2018)). To reduce losses and maximise returns on investments, this information can be used to develop: 1) coordinated, agreed plans for action; 2) a clear, evidence-based decision-making process, and; 3) financing models to ensure that the plans for early action can be implemented (Clarke and Dercon 2016a).

25

7.5.3. Best practices of decision making toward sustainable land management

Sustainable land management is a strategy and also an outcome (Waas et al. 2014) and decision making practices are fundamental in achieving it as an outcome (*medium evidence, medium agreement*). Sustainable land management decision making is improved (*medium evidence and high*

29

1 *agreement*) with ecological service mapping with three characteristics: robustness (robust modelling,
2 measurement, and stakeholder-based methods for quantification of ecosystem service supply, demand
3 and/or flow, as well as measures of uncertainty and heterogeneity across spatial and temporal scales
4 and resolution); transparency (to contribute to clear information-sharing and the creation of linkages
5 with decision support processes); and relevancy to stakeholders (people-central in which stakeholders
6 are engaged at different stages) (Willemsen et al. 2015; Ashcroft et al. 2016). Practices that advance
7 sustainable land management include remediation practices as well as critical interventions that are
8 reshaping norms and standards, joint implementation, experimentation, and integration of rural actors'
9 agency in analysis and approaches in decision-making (Hou and Al-Tabbaa 2014). Best practices are
10 identified in the literature after their implementation demonstrates effectiveness at improving water
11 quality, the environment, or reducing pollution (Rudolph et al. 2015; Lam et al. 2011).

12 There is *medium evidence and medium agreement* about what factors consistently determine the
13 adoption of agricultural best management practices (Herendeen and Glazier 2009) and these
14 positively correlate to education levels, income, farm size, capital, diversity, access to information,
15 and social networks. Attending workshops for information and trust in crop consultants are also
16 important factors in adoption of best management practices (Ulrich-Schad, J.D., Garcia de Jalon, S.,
17 Babin, N., Paper, A. 2017; Baumgart-Getz et al. 2012). More research is needed on the sustained
18 adoption of these factors over time (Prokopy et al. 2008).

19 There is *medium evidence and high agreement* that sustainable land management practices and
20 incentives require mainstreaming into relevant policy; appropriate market based approaches, including
21 payment for ecosystem services and public private partnerships, need better integration into payment
22 schemes (Tengberg et al. 2016). There is *medium evidence and high agreement* that many of the best
23 sustainable land management decisions are made with the participation of stakeholders and social
24 learning (Section 7.6.4) (Stringer and Dougill 2013). As stakeholders may not be in agreement, either
25 practices of mediating agreement, or modelling that depicts and mediates the effects of stakeholder
26 perceptions in decision making may be applicable (Hou 2016; Wiggering and Steinhardt 2015).

27 **7.5.4. Adaptive management**

28 Adaptive management is an evolving approach to natural resource management founded on decision
29 making approaches in other fields (such as business, experimental science, and industrial ecology)
30 (Allen et al. 2011; Williams 2011) and decision making that overcomes management paralysis and
31 mediates multiple stakeholder interests through use of simple steps. (Adaptive governance considers a
32 broader socio-ecological system that includes the social context that facilitates adaptive management
33 (Chaffin et al. 2014)). Adaptive management steps include evaluating a problem and integrating
34 planning, analysis and management into a transparent process to build a road map focused on
35 achieving fundamental objectives. Requirements of success are clearly articulated objectives, the
36 explicit acknowledgment of uncertainty, and a transparent response to all stakeholder interests in the
37 decision making process (Allen et al. 2011). Adaptive management builds on this foundation by
38 incorporating a formal iterative process acknowledging uncertainty and achieving management
39 objectives through a structured feedback process that includes stakeholder participation (see 7.6.4)
40 (Foxon et al. 2009). In the adaptive management process the problem and desired goals are identified,
41 evaluation criteria formulated, the system boundaries and context are ascertained, tradeoffs evaluated,
42 decisions are made regarding responses and policy instruments, which are implemented, and
43 monitored, evaluated and adjusted (Allen et al. 2011). The implementation of policy strategies and
44 monitoring of results occurs in a continuous management cycle of monitoring, assessment and
45 revision (Hurlbert 2015b; Newig et al. 2010; Pahl-Wostl et al. 2007) as illustrated in Figure 7.6.

Adaptive Risk Governance

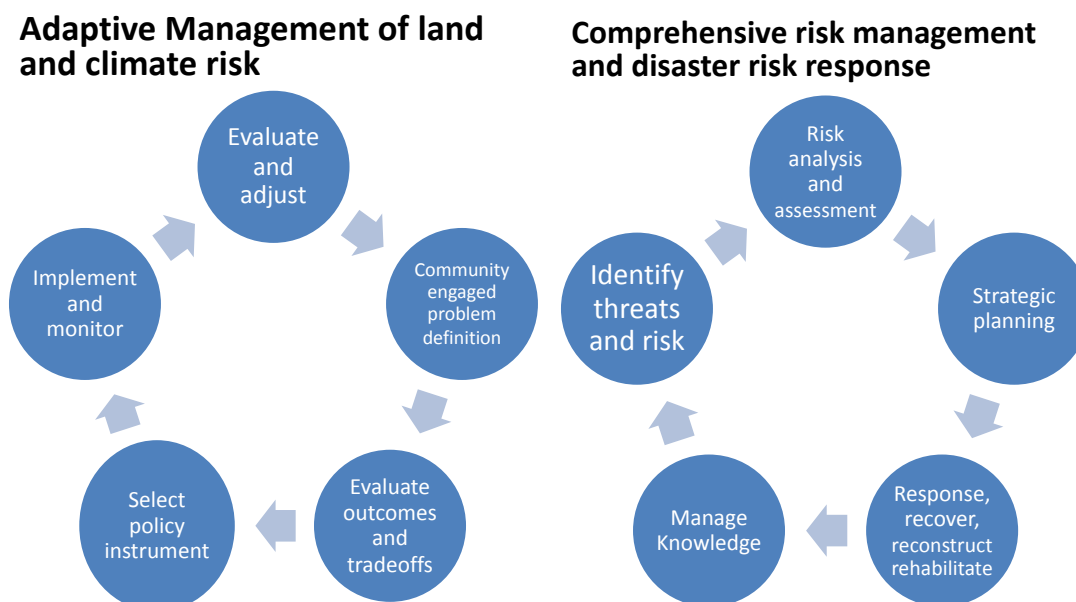

Figure 7.6 Adaptive Governance, Management, and Comprehensive Iterative Risk Management.
Source: Adapted from (Ammann 2013; Allen et al. 2011)

A key focus on adaptive management is the identification and reduction of uncertainty (as described in Chapter 1, 1.2.2 and Cross-Chapter Box 1 on Scenarios) and partial controllability whereby policies used to implement an action are only indirectly responsible (for example setting a harvest rate) (Williams 2011). There is *medium evidence and high agreement* that adaptive management is an ideal method to resolve uncertainty when uncertainty and controllability (resources will respond to management) are both high (Allen et al. 2011). Where uncertainty is high, but controllability is low, developing and analysing scenarios may be more appropriate (Allen et al. 2011). Anticipatory governance has developed combining scenarios and forecasting in order to creatively design strategy to address complex, fuzzy and wicked challenges (Ramos 2014; Quay 2010) (see 7.5). Even where there is low controllability, such as in the case of climate change, adaptive management can help mitigate impacts including changes in water availability and shifting distributions of plants and animals (Allen et al. 2011).

There is *medium evidence and high agreement* that adaptive management can help reduce anthropogenic impacts of changes of land and climate including: species decline and habitat loss (participative identification, monitoring, and review of species at risk as well as decision making surrounding protective measures) (Fontaine 2011; Smith 2011) including quantity and timing of harvest of animals (Johnson 2011a), human participation in natural resource-based recreational activities including selection fish harvest quotas and fishing seasons from year to year (Martin and Pope 2011), managing competing interests of land use planners and conservationists in public lands (Moore et al. 2011), managing endangered species and minimising fire risk through land cover management (Breininger et al. 2014), land use change in hardwood forestry through mediation of hardwood plantation forestry companies and other stakeholders including those interested in water,

1 environment or farming (Leys and Vanclay 2011), and sustainable land management protecting
2 biodiversity, increasing carbon storage, and improving livelihoods (Cowie et al. 2011). There is
3 *medium evidence and medium agreement* that despite abundant literature and theoretical explanation,
4 there has remained imperfect realisation of adaptive management because of several challenges: lack
5 of clarity in definition and approach, few success stories on which to build an experiential base
6 practitioner knowledge of adaptive management, paradigms surrounding management, policy and
7 funding that favour reactive approaches instead of the proactive adaptive management approach,
8 shifting objectives that do not allow for the application of the approach, and failure to acknowledge
9 social uncertainty (Allen et al. 2011). Adaptive management includes participation (7.6.4), the use of
10 indicators (7.5.5), in order to avoid maladaptation and trade-offs while maximising synergies (7.5.6).

11 **7.5.5. Performance indicators**

12 Measuring performance is important in adaptive management decision-making, policy instrument
13 implementation, and governance and can help evaluate policy effectiveness (*medium evidence, high*
14 *agreement*) (Wheaton and Kulshreshtha 2017; Bennett and Dearden 2014; Oliveira Júnior et al. 2016;
15 Kaufmann 2009). Indicators can relate to specific policy problems (climate mitigation, land
16 degradation), sectors (agriculture, transportation etc.), and policy goals (SDGs, food security).

17 It is necessary to monitor and evaluate the effectiveness and efficiency of performing climate actions
18 to ensure the long-term success of *climate* initiatives or plans. Measurable indicators are useful for
19 climate policy development and decision-making process since they can provide quantifiable
20 information regarding the progress of climate actions. The Paris Agreement (UNFCCC 2015)
21 focused on reporting the progress of implementing countries' pledges, i.e., NDCs and national
22 adaptation needs in order to examine the aggregated results of mitigation actions that have already
23 been implemented. For the case of measuring progress toward achieving land degradation neutrality,
24 it was suggested to use land-based indicators, i.e., trend in land cover, trends in land productivity or
25 functioning of the land, and trends in carbon stock above and below ground (Cowie et al. 2018a).
26 There is *medium evidence and high agreement* that indicators for measuring biodiversity and
27 ecosystem services in response to governance at local to international scale meet the criteria of
28 parsimony and scale specificity, are linked to some broad social, scientific and political consensus on
29 desirable states of ecosystems and biodiversity, and include normative aspects such as environmental
30 justice or socially just conservation (Layke 2009) (Van Oudenhoven et al. 2012) (Turnhout et al.
31 2014)(Häyhä and Franzese 2014), (Guerry et al. 2015)(Díaz et al. 2015).

32 Important in making choices of metrics and indicators is understanding that the science, linkages and
33 dynamics in systems are complex, not amenable to be addressed by simple economic instruments, and
34 are often unrelated to short-term management or governance scales (Naeem et al. 2015) (Muradian
35 and Rival 2012). Thus, ideally stakeholders participate in the selection and use of indicators for
36 biodiversity and ecosystem services and monitoring impacts of governance and management regimes
37 on land-climate interfaces. The adoption of non-economic approaches that are part of the emerging
38 concept of Nature's Contributions to People (NCP) could potentially elicit support for conservation
39 from diverse sections of civil society (Pascual et al. 2017).

40 Recent studies increasingly incorporate the role of stakeholders and decision makers in selection of
41 indicators for land systems (Verburg et al. 2015) including sustainable agriculture (Kanter et al.
42 2016), bioenergy sustainability (Dale et al. 2015), desertification (Liniger et al. 2019), and
43 vulnerability (Debortoli et al. 2018). Kanter et al. (2016) propose a four-step cradle-to-grave approach
44 for agriculture trade-off analysis, which involves co-evaluation of indicators and trade-offs with both
45 stakeholders and decision-makers.

46

1 **7.5.6. Maximising Synergies and Minimising Trade-offs**

2 Synergies and trade-offs to address land and climate related measures are identified and discussed in
3 Chapter 6. Here we outline policies supporting Chapter 6 response options (see Table 7.5), and
4 discuss synergies and trade-offs in policy choices and interactions among policies. Trade-offs will
5 exist between broad policy approaches. For example, while legislative and regulatory approaches may
6 be effective at achieving environmental goals, they may be costly and ideologically unattractive in
7 some countries. Market-driven approaches such as carbon pricing are cost effective ways to reduce
8 emissions, but may not be favoured politically and economically (see 7.4.4). Information provision
9 involves little political risk or ideological constraints, but behavioural barriers may limit their
10 effectiveness (Henstra 2016). This level of trade-off is often determined by the prevailing political
11 system.

12 Synergies and trade-offs also result from interaction between policies (policy interplay (Urwin and
13 Jordan 2008)) at different levels of policy (vertical) and across different policies (horizontal) (see also
14 section on policy coherence, 7.4.8)). If policy mixes are designed appropriately, acknowledging and
15 incorporating trade-offs and synergies, they are better placed to deliver an outcome such as
16 transitioning to sustainability (Howlett and Rayner 2013; Huttunen et al. 2014) (*medium evidence and*
17 *medium agreement*). However, there is *limited evidence and medium agreement* that evaluating
18 policies for coherence in responding to climate change and its impacts is not occurring, and policies
19 are instead reviewed in a fragmented manner (Hurlbert and Gupta 2016).

20

1

Table 7.5 Selection of Policies/Programmes/Instruments that support response options

Category	Integrated Response Option	Policy instrument supporting response option
Land management in agriculture	Increased food productivity	Investment in agricultural research for crop and livestock improvement, agricultural technology transfer, inland capture fisheries and aquaculture {7.4.7} agricultural policy reform and trade liberalisation
	Improved cropland, grazing, and livestock management	Environmental farm programs/agri-environment schemes, water efficiency requirements and water transfer {3.7.5}, extension services
	Agroforestry	Payment for ecosystem services {7.4.6}
	Agricultural diversification	Elimination of agriculture subsidies {5.7.1}, environmental farm programs, agri-environmental payments {7.4.6}, rural development programmes
	Reduced grassland conversion to cropland	Elimination of agriculture subsidies, remove insurance incentives, ecological restoration {7.4.6}
	Integrated water management	Integrated governance {7.6.2}, multi-level instruments {7.4.1}
Land management in forests	Forest management, Reduced deforestation and degradation, Reforestation and forest restoration, Afforestation	REDD+, forest conservation regulations, payments for ecosystem services, recognition of forest rights and land tenure {7.4.6}, adaptive management of forests {7.5.4}, land use moratoriums, reforestation programs and investment {4.9.1}
Land management of soils	Increased soil organic carbon content, Reduced soil erosion, Reduced soil salinisation, Reduced soil compaction, Biochar addition to soil	Land degradation neutrality {7.4.5}, drought plans, flood plans, flood zone mapping {7.4.3}, technology transfer {7.4.4}, land use zoning {7.4.6}, ecological service mapping and stakeholder based quantification {7.5.3}, environmental farm programs/agri-environment schemes, water efficiency requirements and water transfer {3.7.5}
Land management in all other ecosystems	Fire management	Fire suppression, prescribed fire management, mechanical treatments {7.4.3}
	Reduced landslides and natural hazards	Land use zoning {7.4.6}
	Reduced pollution - acidification	Environmental regulations, Climate mitigation (carbon pricing) {7.4.4}
	Management of invasive species / encroachment	Invasive species regulations, trade regulations {5.7.2, 7.4.6}
	Restoration and reduced conversion of coastal wetlands	Flood zone mapping {7.4.3}, land use zoning {7.4.6}
	Restoration and reduced conversion of peatlands	Payment for ecosystem services {7.4.6; 7.5.3}, standards and certification programs {7.4.6}, land use moratoriums
CDR Land management	Biodiversity conservation	Conservation regulations, protected areas policies
Demand management	Enhanced weathering of minerals	No data
	Bioenergy and BECCS	Standards and certification for sustainability of biomass and land use {7.4.6}
Supply management	Dietary change	Awareness campaigns/education, changing food choices through nudges, synergies with health insurance and policy {5.7.2}
	Reduced post-harvest losses	Agricultural business risk programs {7.4.8}; regulations to reduce and taxes on food waste, Improved shelf life, circularising the economy to produce substitute goods, carbon pricing, sugar/fat taxes {5.7.2}
	Reduced food waste (consumer or retailer), Material substitution	
Risk management	Sustainable sourcing	Food labelling, innovation to switch to food with lower environmental footprint, public procurement policies {5.7.2}, standards and certification programs {7.4.6}
	Management of supply chains	Liberalised international trade {5.7.2}, food purchasing and storage policies of governments, standards and certification programs {7.4.6}, regulations on speculation in food systems
	Enhanced urban food systems	Buy local policies; land use zoning to encourage urban agriculture, nature-based solutions and green infrastructure in cities; incentives for technologies like vertical farming
	Improved food processing and retailing, Improved energy use in food systems	Agriculture emission trading {7.4.4}; investment in research and development for new technologies; certification
Risk management	Management of urban sprawl	Land use zoning {7.4.6}
	Livelihood diversification	Climate-smart agriculture policies, adaptation policies, extension services {7.5.6}
	Disaster risk management	Disaster risk reduction {7.5.4; 7.4.3}, adaptation planning
	Risk sharing instruments	Insurance, iterative risk management, Cat bonds, risk layering, contingency funds {7.4.3}, agriculture business risk portfolios {7.4.8}

2

Cross-Chapter Box 9 on Illustrative Climate and Land Pathways

Katherine Calvin (The United States of America), Edouard Davin (France/Switzerland), Margot Hurlbert (Canada), Jagdish Krishnaswamy (India), Alexander Popp (Germany), Prajal Pradhan (Nepal/Germany)

Future development of socioeconomic factors and policies influence the evolution of the land-climate system, among others in terms of the land used for agriculture and forestry. Climate mitigation policies can also have a major impact on land use, especially in scenarios consistent with the climate targets of the Paris Agreement. This includes the use of bio-energy or Carbon Dioxide Removal (CDR), such as bioenergy with carbon dioxide capture and storage (BECCS) and afforestation. Land-based mitigation options have implications for GHG fluxes, desertification, land degradation, food insecurity, ecosystem services and other aspects of sustainable development.

Illustrative Futures

The three illustrative futures are based on the Shared Socioeconomic Pathways (SSPs; (O'Neill et al. 2014c; Riahi et al. 2017b; Popp et al. 2017; Rogelj et al. 2018b); Cross-Chapter Box 1 in Chapter 1). SSP1 is a scenario with a broad focus on sustainability including a focus on human development, technological development, nature conservation, globalised economy, economic convergence and early international cooperation including moderate levels of trade. The scenario assumes a low population growth, relatively high agricultural yields and a move towards less-meat intensive diets (van Vuuren et al. 2017b). Dietary change and reductions in food waste reduce agricultural demands and well-managed land systems enable reforestation and/or afforestation. SSP2 is a scenario in which societal as well as technological development follows historical patterns (Fricko et al. 2017). Land-based CDR is achieved through bioenergy and BECCS, and to a lesser degree by afforestation and reforestation. SSP3 is a scenario with limited technological progress and land-use regulation. Agricultural demands are high due to resource-intensive consumption and a regionalised world leads to reduced flows for agricultural goods. In SSP3, forest mitigation activities and abatement of agricultural GHG emissions are limited due to major implementation barriers such as low institutional capacities in developing countries and delayed as a consequence of low international cooperation (Fujimori et al. 2017a). Emissions reductions are achieved primarily through the energy sector, including the use of bioenergy and BECCS.

Policies in the Illustrative Futures

SSPs are complemented by a set of shared policy assumptions (Kriegler et al. 2014), indicating the types of policies that may be implemented in each future world. IAMs represent the effect of these policies on the economy, energy system, land use and climate with the caveat that they are assumed to be effective or in some cases the policy goals (e.g., dietary change) are imposed rather than explicitly modelled. In the real world, there are various barriers that can make policy implementation more difficult (see 7.4.9). These barriers will be generally higher in SSP3 than SSP1.

SSP1: A number of policies could support this SSP1 future including: effective carbon pricing, emission trading schemes (including net CO₂ emissions from agriculture), carbon taxes, regulations limiting GHG emissions and air pollution, forest conservation (mix of land-sharing and land sparing) through participation, incentives for ecosystem services and secure tenure, and protecting the environment, microfinance, crop and livelihood insurance, agriculture extension services, agricultural production subsidies, low export tax and import tariff rates on agricultural goods, dietary awareness campaigns, regulations to reduce and taxes on food waste, improved shelf life, sugar/fat taxes, and instruments supporting sustainable land management including payment for ecosystem services, land use zoning, REDD+, standards and certification for sustainable biomass production practices, legal reforms on land ownership and access, legal aid, legal education, including reframing these policies as

entitlements for women and small agricultural producers (rather than sustainability) (O'Neill et al. 2017; van Vuuren et al. 2017b) (see 7.4).

SSP2: The same policies that support the SSP1 could support the SSP2 but may be less effective and only moderately successful. Policies may be challenged by adaptation limits (7.4.9), inconsistency in formal and informal institutions in decision making (7.5.1) or result in maladaptation (7.4.7). Moderately successful sustainable land management policies result in some land competition. Land degradation neutrality is moderately successful. Successful policies include those supporting bioenergy and BECCS (Rao et al. 2017; Riahi et al. 2017b; Fricko et al. 2017) (see 7.4.6).

SSP3: Policies that exist in SSP1 may or may not exist in SSP3, and are ineffective (O'Neill et al. 2014c). There are challenges to implementing these policies, as in SSP2. In addition, ineffective sustainable land management policies result in competition for land between agriculture and mitigation. Land degradation neutrality is not achieved (Riahi et al. 2017b). Successful policies include those supporting bioenergy and BECCS (see 7.4.6) (Kriegler et al. 2017; Fujimori et al. 2017a; Rao et al. 2017). Demand side food policies are absent and supply side policies predominate. There is no success in advancing land ownership and access policies for agricultural producer livelihood (7.6.5).

Land use and land cover change

Agricultural area in SSP1 declines as a result of the low population growth, agricultural intensification, low meat consumption, and low food waste. In contrast, SSP3 has high population and strongly declining rates of crop yield growth over time, resulting in increased agricultural land area. The SSP2 falls somewhere in between, with its modest growth in all factors. In the climate policy scenarios consistent with the Paris Agreement, bioenergy/BECCS and reforestation/afforestation play an important role in SSP1 and SSP2. The use of these options, and the impact on land, is larger in scenarios that limit radiative forcing in 2100 to 1.9 Wm^{-2} than in the 4.5 Wm^{-2} scenarios. In SSP3, the expansion of land for agricultural production implies that the use of land-related mitigation options is very limited, and the scenario is characterised by continued deforestation.

Cross-Chapter Box 9 Figure 1: Changes in agricultural land (left), energy cropland (middle) and forest cover (right) under three different SSPs (colours) and two different warming levels (rows). Agricultural land includes both pasture and non-energy cropland. Colours indicate SSPs, with SSP1 shown in green,

SSP2 in blue, and SSP3 in red. Shaded area show the range across all IAMs; lines show the median across all models. Models are only included in a figure if they provided results for all SSPs in that panel. There is no SSP3 in the top row, as 1.9 Wm^{-2} is infeasible in this world. Data is from an update of the IAMC Scenario Explorer developed for the SR15 (Huppmann et al. 2018; Rogelj et al. 2018a).

Implications for mitigation and other land challenges

The combination of baseline emissions development, technology options, and policy support makes it much easier to reach the climate targets in the SSP1 scenario than in the SSP3 scenario. As a result, carbon prices are much higher in SSP3 than in SSP1. In fact, the 1.9 Wm^{-2} target was found to be infeasible in the SSP3 world (Cross-Chapter Box 9 Table 1). Energy system CO_2 emissions reductions are greater in the SSP3 than in the SSP1 to compensate for the higher land-based CO_2 emissions.

Accounting for mitigation and socioeconomics alone, food prices (an indicator of food insecurity) are higher in SSP3 than in the SSP1 and higher in the 1.9 Wm^{-2} than in the 4.5 Wm^{-2} (Cross-Chapter Box 9 Table 1). Forest cover is higher in the SSP1 than the SSP3 and higher in the 1.9 Wm^{-2} than in the 4.5 Wm^{-2} . Water withdrawals and water scarcity are in general higher in the SSP3 than the SSP1 (Hanasaki et al. 2013a; Graham et al. 2018b) and higher in scenarios with more bioenergy (Hejazi et al. 2014c); however, these indicators have not been quantified for the specific SSP-RCP combinations discussed here.

Climate change, results in higher impacts and risks in the 4.5 Wm^{-2} world than in the 1.9 Wm^{-2} world for a given SSP and these risks are exacerbated in SSP3 compared to SSP1 and SSP2 due to population's higher exposure and vulnerability. For example, the risk of fire is higher in warmer worlds; in the 4.5 Wm^{-2} world, the population living in fire prone regions is higher in the SSP3 (646 million) than in the SSP2 (560 million) (Knorr et al. 2016). Global exposure to multi-sector risk quadruples between the 1.5°C^1 and 3°C and is a factor of six higher in the SSP3- 3°C than in the SSP1- 1.5°C (Byers et al. 2018). Future risks resulting from desertification, land degradation and food insecurity are lower in the SSP1 compared to SSP3 at the same level of warming. For example, the transition moderate to high risk of food insecurity occurs between 1.3 and 1.7°C for the SSP3, but not until 2.5 to 3.5°C in the SSP1 (Section 7.2).

Table 1: Quantitative indicators for the illustrative pathways. Each cell shows the mean, minimum, and maximum value across IAM models for each indicator and each pathway in 2050 and 2100. All IAMs that provided results for a particular pathway are included here. Note that these indicators exclude the implications of climate change. Data is from an update of the IAMC Scenario Explorer developed for the SR15 (Huppmann et al. 2018; Rogelj et al. 2018b).

		SSP1		SSP2		SSP3	
		1.9 Wm^{-2} mean (min, max)	4.5 Wm^{-2} mean (min, max)	1.9 Wm^{-2} mean (min, max)	4.5 Wm^{-2} mean (min, max)	1.9 Wm^{-2} mean (min, max)	4.5 Wm^{-2} mean (min, max)

Cumulative AFOLU CO ₂ Emissions until 2100 (GtCO ₂)		-127.3 (5.9, -683.0)	-54.9 (52.1, -545.2)	-126.8 (153.0, -400.7)	40.8 (277.0, -372.9)	N/A	188.8 (426.6, 77.9)

^a The SSP2-19 is infeasible in two models. One of these models sets the maximum carbon price in the SSP1-19; the carbon price range is smaller for the SSP2-19 as this model is excluded there. Carbon prices are higher in the SSP2-19 than the SSP1-19 for every model that provided both simulations.

^a Food demand estimates include waste.

^b Animal product demand includes meat and dairy.

Summary

Future pathways for climate and land use include portfolios of response and policy options. Depending on the response options included, policy portfolios implemented, and other underlying socioeconomic drivers, these pathways result in different land-use consequences and their contribution to climate change mitigation. Agricultural area declines by more than 5 Mkm² in one SSP but increases by as much as 5 Mkm² in another. The amount of energy cropland ranges from nearly zero to 11 Mkm², depending on the SSP and the warming target. Forest area declines in the SSP3 but increases substantially in the SSP1. Subsequently, these pathways have different implications for risks related to desertification, land degradation, food insecurity, and terrestrial greenhouse gas fluxes, as well as ecosystem services, biodiversity, and other aspects of sustainable development.

7.5.6.1. Trade-offs and Synergies between ES

Unplanned or unintentional trade-offs and synergies between policy driven response options related to ecosystem service (ES) can happen over space (e.g., upstream-downstream, IWM 3.7.5.2) or intensify over time (reduced water in future dry-season due to growing tree plantations, 6.4.1). Trade-offs can occur between two or more ecosystem services (land for climate mitigation vs food 6.2, 6.3, 6.4, Cross-Chapter Box 8: Ecosystem services, Chapter 6; Cross-Chapter Box 9: Illustrative climate and land pathways, Chapter 6), and between scales such as forest biomass based livelihoods versus global ES carbon storage (Chhatre and Agrawal 2009)(*medium evidence, medium agreement*). Tradeoffs can be reversible or irreversible (Rodríguez et al. 2006; Elmqvist et al. 2013)(for example a soil carbon sink is reversible (6.4.1.1)

Although there is *robust evidence* and *high agreement* that ES are important for human well-being, the relationship between poverty alleviation and ES can be surprisingly complex, understudied and dependent on the political economic context; current evidence is largely about provisioning services and often ignores multiple dimensions of poverty (Suich et al. 2015; Vira et al. 2012). Spatially explicit mapping and quantification of stake-holder choices vis-à-vis distribution of various ES can help enhance synergies and reduce trade-offs (Turkelboom et al. 2018; Locatelli et al. 2014)(see 7.5.5).

7.5.6.2. Sustainable Development Goals (SDGs): Synergies and Trade-offs

The SDGs, an international persuasive policy instrument, apply to all countries, and measure sustainable and socially just development of human societies at all scales of governance (Griggs et al. 2013). The UN SDGs rest on the premise that the goals are mutually reinforcing and there exist inherent linkages, synergies and trade-offs (to a greater or lesser extent) between and within the sub-goals (Fuso Nerini et al. 2018; Nilsson et al. 2016b)(Le Blanc 2015). There is *high confidence* that opportunities, trade-offs and co-benefits are context and region specific and depend on a variety of political, national and socio-economic factors (Nilsson et al. 2016b) depending on perceived importance by decision and policy makers (Figure 7.7, Table 7.6 below). Aggregation of targets and indicators at the national level can mask severe biophysical and socio-economic trade-offs at local and regional scales (Wada et al. 2016).

There is *medium evidence* and *high agreement* that SDGs must not be pursued independently, but in a manner that recognises trade-offs and synergies with each other, consistent with a goal of ‘policy coherence.’ Policy coherence also refers to spatial trade-offs and geo-political implications within and between regions and countries implementing SDGs. For instance, supply side food security initiatives of land-based agriculture are impacting marine fisheries globally through creation of dead-zones due to agricultural run-off (Diaz and Rosenberg 2008).

SDG 7 (Affordable and clean energy) and efficient and less carbon intensive transportation (SDG 7 and 9) are important SDGs related to mitigation with adaptation co-benefits, but have local trade-offs with biodiversity and competing uses of land and rivers (see Case Study: Green Energy: Biodiversity Conservation vs Global Environment Targets) (*medium evidence, high agreement*) (Bogardi et al. 2012) (Nilsson and Berggren 2000; Hoeninghaus et al. 2009) (Winemiller et al. 2016). This has occurred despite emerging knowledge about the role that rivers and riverine ecosystems play in human development and in generating global, regional and local ecosystem services (Nilsson and Berggren 2000; Hoeninghaus et al. 2009). The transformation of river ecosystems for irrigation, hydropower and water requirements of societies worldwide is the biggest threat to fresh-water and estuarine biodiversity and

1 ecosystems services (Nilsson and Berggren 2000; Vörösmarty et al. 2010). These projects
2 address important energy and water-related demands, but their economic benefits are often
3 overestimated in relation to trade-offs with respect to food (river capture fisheries),
4 biodiversity and downstream ecosystem services (Winemiller et al. 2016). Some trade-offs
5 and synergies related to SDG7 impact aspirations of greater welfare and well-being, as
6 well as physical and social infrastructure for sustainable development (Fuso Nerini et al.
7 2018)(see 7.5.6.1 where tradeoffs exist between climate mitigation and food).

8 There are also spatial trade-offs related to large river diversion projects and export of
9 “virtual water” through water intensive crops produced in one region exported to another,
10 with implications for food-security, water security and downstream ecosystem services of
11 the exporting region (Hanasaki et al. 2010; Verma et al. 2009). Synergies include cropping
12 adaptation that increase food system production and eliminate hunger (SDG2) (Rockström et
13 al. 2017; Lipper et al. 2014a; Neufeldt et al. 2013). Well-adapted agricultural systems have
14 shown to have synergies - positive returns on investment and contribution to safe drinking
15 water, health, biodiversity and equity goals (DeClerck 2016). Assessing the water footprint
16 of different sectors at the river basin scale can provide insights for interventions and decision
17 making(Zeng et al. 2012)

18 Sometimes the trade-offs in SDGs can arise in the articulation and nested hierarchy of
19 seventeen goals and targets under them. In terms of aquatic life and ecosystems, there is an
20 explicit SDG for sustainable management of marine life (SDG 14, Life below Water). There
21 is no equivalent goal exclusively for fresh-water ecosystems, but hidden under SDG 6
22 (Clean Water and Sanitation) out of 6 listed targets, the sixth target is about protecting and
23 restoring water-related ecosystems, which suggests a lower order of global priority
24 compared to being listed as a goal in itself (e.g., SDG 14).

25 There is *limited evidence and limited agreement* that binary evaluations of individual SDGs
26 and synergies and trade-offs that categorise interactions as either ‘beneficial’ or ‘adverse’
27 may be subjective and challenged further by the fact that feedbacks can often not be
28 assigned as unambiguously positive or negative (Blanc et al. 2017). The Special Report on
29 Global Warming of 1.5°C notes, “A reductive focus on specific SDGs in isolation may
30 undermine the long-term achievement of sustainable climate change mitigation” (Holden et
31 al. 2017). Greater work is needed to tease out these relationships; studies that include
32 quantitative modelling (see Karnib 2017) and nuanced scoring scales (ICSU 2017) of these
33 relationships have started.

34 A nexus approach is increasingly being adopted to explore synergies and trade-offs between
35 a select subset of goals and targets (such as the interaction between water, energy, and food
36 (see, e.g., Yumkella and Yillia 2015; Conway et al. 2015; Ringler et al. 2015)). However,
37 even this approach ignores systemic properties and interactions across the system as a whole
38 (Weitz et al. 2017a). Pursuit of certain targets in one area can generate rippling effects across
39 the system, and these effects in turn can have secondary impacts on yet other targets. (Weitz
40 et al. 2017a) found that SDG target 13.2 (climate change policy/ planning) is influenced by
41 actions in six other targets. SDG 13.1 (climate change adaption) and also 2.4 (food
42 production) receive the most positive influence from progression in other targets.

43 There is *medium evidence and high agreement* that to be effective, truly sustainable, and to
44 reduce or mitigate emerging risks, SDGs need knowledge dissemination and policy
45 initiatives that recognise and assimilate concepts of co-production of ecosystem services in
46 socio-ecological systems, cross-scale linkages, uncertainty, spatial and temporal trade-offs

1 between SDGs and ecosystem services that recognise biophysical, social and political
 2 constraints and an understanding of how social change occurs at various scales (Rodríguez et
 3 al. 2006; Norström et al. 2014; Palomo et al. 2016). Several methods and tools are proposed
 4 in literature to address and understand SDG interactions. Nilsson et al. (2016a) suggest
 5 going beyond a simplistic synergies-trade-offs framing to understanding various relationship
 6 dimensions proposing a seven-point scale to understand these interactions.

7 This approach, and the identification of clusters of synergy, can help indicate that
 8 government ministries work together or establish collaborations to reach their specific goals.
 9 Finally, context specific analysis is needed. Synergies and trade-offs will depend on the
 10 natural resource base (such as land or water availability), governance arrangements,
 11 available technologies, and political ideas in a given location (Nilsson et al. 2016b). Figure
 12 7.7 below shows that at the global scale there is less uncertainty in the evidence surrounding
 13 SDGs, but also less agreement on norms, priorities and values for SDG implementation.
 14 Although there is some agreement on the regional and local scale surrounding SDGs, there is
 15 higher certainty on the science surrounding ESs.

Retaining existing forests, restoring degraded forest and afforestation are response options for climate change mitigation with adaptation benefits (6.4.1). Policies at various levels of governance that foster ownership, autonomy, and provide incentives for forest cover can reduce trade-off between carbon sinks in forests and local livelihoods (especially when the size of forest commons is sufficiently large) (Chhatre and Agrawal 2009; Locatelli et al. 2014) (see Table 7.6 this section, Case Study: Forest conservation instruments: REDD+ in the Amazon and India, 7.4.6).

Forest restoration for mitigation through carbon sequestration and other ecosystem services or co-benefits (e.g., hydrologic, NTFP, timber and tourism) can be passive or active (although both types largely exclude livestock). Passive restoration is more economically viable in relation to restoration costs as well as co-benefits in other ESs, calculated on a NPV basis, especially under flexible carbon credits (Cantarello et al. 2010). Restoration can be more cost effective with positive socioeconomic and biodiversity conservation outcomes, if costly and simplistic planting schemes are avoided (Menz et al. 2013). Passive restoration takes longer to demonstrate co-benefits and net economic gains, can be confused with land abandonment in some regions and countries, and therefore secure land-tenure at individual or community scales is important for its success (Zahawi et al. 2014). Potential approaches include improved markets and payment schemes for ecosystem services (Tengberg et al. 2016)(see

1 7.4.6). Proper targeting of incentive schemes and reducing poverty through access to ecosystem
2 services requires knowledge regarding the distribution of beneficiaries and about those whose
3 livelihoods are likely to be impacted in what manner (Nayak et al. 2014; Loaiza et al. 2015; Vira et al.
4 2012). Institutional arrangements to govern ecosystems are believed to synergistically influence
5 maintenance of carbon storage and forest based livelihoods, especially when they incorporate local
6 knowledge and decentralised decision making (Chhatre and Agrawal 2009). Earning carbon credits
7 from reforestation with native trees involves a higher cost of the certification and validation processes,
8 increasing the temptation to choose fast-growing (perhaps non-native) species with consequences for
9 native biodiversity. Strategies and policies that aggregate landowners or forest dwellers are needed to
10 reduce the cost to individuals and payment for ecosystem services (PES) schemes can generate
11 synergies (Bommarco et al. 2013; Chhatre and Agrawal 2009). Bundling several PES schemes that
12 address more than one ES can increase income generated by forest restoration (Brancalion et al.
13 2012). In the forestry sector, there is evidence that adaptation and mitigation can be fostered in
14 concert. A recent assessment of the California forest offset program shows that such programs, by
15 compensating individuals and industries for forest conservation, can deliver mitigation and
16 sustainability co-benefits (Anderson et al. 2017). Adaptive forest management focussing on re-
17 introducing native tree species can provide both mitigation and adaptation benefit by reducing fire
18 risk and increasing carbon storage (Astrup et al. 2018).

19 In the agricultural sector, there has been little published empirical work on interactions between
20 adaptation and mitigation policies. Smith and Oleson (2010) describe potential relationships,
21 focussing particularly on the arable sector and predominantly on mitigation efforts and more on
22 measures than policies. The considerable potential of the agro-forestry sector for synergies and
23 contributing to increasing resilience of tropical farming systems is discussed in (Verchot et al. 2007)
24 with examples from Africa.

25 ‘Climate Smart Agriculture’ has emerged in recent years as an approach to integrate food security and
26 climate challenges. The three pillars of CSA are to: (1) adapt and build resilience to climate change;
27 (2) reduce GHG emissions, and; (3) sustainably increase agricultural productivity, ultimately
28 delivering ‘triple-wins’ (Lipper et al. 2014c). While the concept is conceptually appealing, a range of
29 criticisms, contradictions and challenges exist in using CSA as the route to resilience in global
30 agriculture, notably around the political economy (Newell and Taylor 2017), the vagueness of the
31 definition, and consequent assimilation by the mainstream agricultural sector, as well as issues around
32 monitoring, reporting and evaluation (Arakelyan et al. 2017).

33 Land-based mitigation is facing important trade-offs with food production, biodiversity and local bio-
34 geophysical effects (Humpeöder et al. 2017; Krause et al. 2017; Robledo-Abad et al. 2017; Boysen
35 et al. 2016, 2017a,b). Synergies between bio energy and food security could be achieved by investing
36 in a combination of instruments including technology and innovations, infrastructure, pricing, flex
37 crops, and improved communication and stakeholder engagement (Kline et al. 2017). Managing these
38 trade-offs might also require demand side interventions including dietary change incentives (see
39 5.7.1).

40 Synergies and trade-offs also result from interaction between policies (policy interplay (Urwin and
41 Jordan 2008)) at different levels of policy (vertical) and across different policies (horizontal) – see
42 also section on policy coherence. If policy mixes are designed appropriately, acknowledging and
43 incorporating trade-offs and synergies, they are more apt to deliver an outcome such as transitioning
44 to sustainability (Howlett and Rayner 2013; Huttunen et al. 2014) (*medium evidence and medium
45 agreement*). However, there is *medium evidence and medium agreement* that evaluating policies for
46 coherence in responding to climate change and its impacts is not occurring, and policies are instead
47 reviewed in a fragmented manner (Hurlbert and Gupta 2016).

1 In the forestry sector, there is evidence that adaptation and mitigation can be fostered in concert. A
2 recent assessment of the California forest offset program shows that such programs, by compensating
3 individuals and industries for forest conservation, can deliver mitigation and sustainability co-benefits
4 (Anderson et al. 2017). Adaptive forest management focussing on re-introducing native tree species
5 can provide both mitigation and adaptation benefit by reducing fire risk and increasing carbon storage
6 (Astrup et al. 2018).

7 Land-based mitigation is facing important trade-offs with food production, biodiversity and local bio
8 geophysical effects (Humpenöder et al. 2017; Krause et al. 2017; Robledo-Abad et al. 2017; Boysen
9 et al. 2016, 2017a,b). Synergies between bio energy and food security could be achieved by investing
10 in a combination of instruments including technology and innovations, infrastructure, pricing, flex
11 crops, and improved communication and stakeholder engagement (Kline et al. 2017). Managing these
12 trade-offs might also require demand side interventions including dietary change incentives.

14 **7.5.6.4. Water, food and aquatic ES**

15 Trade-offs between some types of water use (eg irrigation for food security) and other ecosystem
16 services are expected to intensify under climate change (Hanjra and Ejaz Qureshi 2010). There is an
17 urgency to develop approaches to understand and communicate this to policy and decision makers
18 (Zheng et al. 2016). Reducing water use in agriculture (Mekonnen and Hoekstra 2016) through
19 policies on both supply and demand side such as shift to less-water intensive crops (Richter et al.
20 2017; Fishman et al. 2015), and shift in diets (Springmann et al. 2016) has potential to reduce trade-
21 offs between food security and fresh-water aquatic ecosystem services (*medium evidence, high*
22 *agreement*). There is strong evidence that improved efficiency in irrigation can actually increase
23 overall water use in agriculture and therefore its contribution to improved flows in rivers is
24 questionable (Ward and Pulido-Velazquez 2008).

25 There are now powerful new analytical approaches, high-resolution data and decision making tools
26 that help to predict cumulative impacts of dams, assess trade-offs between engineering and
27 environmental goals, and can help funders and decision makers compare alternative sites or designs
28 for dam building as well as manage flows in regulated rivers based on experimental releases and
29 adaptive learning. This could minimise ecological costs and maximise synergies with other
30 development goals under climate change (Poff et al. 2003; Winemiller et al. 2016). Furthermore the
31 adoption of metrics based on the emerging concept of Nature’s Contributions to People (NCP) under
32 the IPBES framework brings in non-economic instruments and values that in combination with
33 conventional valuation of ecosystem services approaches could elicit greater support for non-
34 consumptive water use of rivers for achieving SDG goals (De Groot et al. 2010; Pascual et al. 2017).

36 **7.5.6.5. Considering Synergies and Tradeoffs to Avoid Maladaptation**

37 Coherent policies that consider synergies and tradeoffs can also reduce the likelihood of
38 maladaptation, which is the opposite of sustainable adaptation (Magnan et al. 2016). Sustainable
39 adaptation is adaptation that “contributes to socially and environmentally sustainable development
40 pathways including both social justice and environmental integrity” (Eriksen et al. 2011). In AR5
41 there was *medium evidence* and *high agreement* that maladaptation is ‘a cause of increasing concern
42 to adaptation planners, where intervention in one location or sector could increase the vulnerability of
43 another location or sector, or increase the vulnerability of a group to future climate change’ (Noble et
44 al. 2014). AR5 recognised that maladaptation arises not only from inadvertent, badly planned
45 adaptation actions, but also from deliberate decisions where wider considerations place greater
46 emphasis on short-term outcomes ahead of longer-term threats, or that discount, or fail to consider,
47 the full range of interactions arising from planned actions (Noble et al. 2014).

1 Some maladaptations are only beginning to be recognised as we become aware of unintended
2 consequences of decisions. An example prevalent across many countries is irrigation as an adaptation
3 to water scarcity. During a drought from 2007–2009 in California, farmers adapted by using more
4 groundwater thereby depleting groundwater elevation by 15 metres. This volume of groundwater
5 depletion is unsustainable environmentally and also emits GHG emissions during the pumping
6 (Christian-Smith et al. 2015). Despite the three years of drought, the agricultural sector performed
7 financially well, due to the groundwater use and crop insurance payments. Drought compensation
8 programmes through crop insurance policies may reduce the incentive to shift to lower water-use
9 crops, thereby perpetuating the maladaptive situation. Another example of maladaptation that may
10 appear as adaptation to drought is pumping out groundwater and storing in surface farm ponds with
11 consequences for water justice, inequity and sustainability (Kale 2017). These examples highlights
12 both the potential for maladaptation from farmers’ adaptation decisions as well as the unintended
13 consequences of policy choices and illustrates the findings of Barnett and O’Neill (2010) that
14 maladaptation can include high opportunity costs (including economic, environmental, and social);
15 reduced incentives to adapt (adaptation measures that reduce incentives to adapt by not addressing
16 underlying causes); and path dependency or trajectories that are difficult to change.

17 In practice, maladaptation is a specific instance of policy incoherence, and it may be useful to develop
18 a framework in designing policy to avoid this type of trade-off. This would specify the type, aim and
19 target audience of an adaptation action, decision, project, plan, or policy designed initially for
20 adaptation, but actually at high risk of inducing adverse effects either on the system in which it was
21 developed, or another connected system, or both. The assessment requires identifying system
22 boundaries including temporal and geographical scales at which the outcome are assessed (Magnan
23 2014; Juhola et al. 2016). National level institutions that cover the spectrum of sectors affected, or
24 enhanced collaboration between relevant institutions is expected to increase the effectiveness of
25 policy instruments, as are joint programmes and funds (Morita and Matsumoto 2018).

26 As new knowledge about trade-offs and synergies amongst land-climate processes emerges regionally
27 and globally, concerns over emerging risks and the need for planning policy responses grow. There is
28 *medium evidence and medium agreement* that trade-offs currently do not figure into existing climate
29 policies including NDCs and SDGs being vigorously pursued by some countries (Woolf et al. 2018).
30 For instance, the biogeophysical co-benefits of reduced deforestation and re/afforestation measures
31 (Chapter 6) are usually not accounted for in current climate policies or in the NDCs, but there is
32 increasing scientific evidence to include them as part of the policy design (Findell et al. 2017; Hirsch
33 et al. 2018; Bright et al. 2017).

34

35 **Case Study: Green Energy: Biodiversity Conservation vs Global Environment Targets?**

36

37 Green and renewable energy and transportation are emerging as an important part of climate change
38 mitigation globally (*medium evidence, high agreement*) (McKinnon 2010; Zarfl et al. 2015; Creutzig
39 et al. 2017). Evidence is however emerging across many biomes (from coastal to semi-arid and
40 humid) how green energy may have significant trade-offs with biodiversity and ecosystem services
41 thus demonstrating the need for closer environmental scrutiny and safeguards (Gibson et al.
42 2017)(Hernandez et al. 2015). In most cases, the accumulated impact of pressures from decades of
43 land-use and habitat loss set the context within which the potential impacts of renewable energy
44 generation need to be considered.

45

46 Small hydropower or SHPs were until recently considered as environmentally benign compared to
47 large dams and are poorly understood, especially since the impacts of clusters of small dams are just
48 becoming evident (Mantel et al. 2010; Fencel et al. 2015; Kibler and Tullos 2013). SHPs (<25/30 MW)
49 and being labelled “green” are often exempt from environmental scrutiny (Abbasi and Abbasi 2011;

1 Pinho et al. 2007; Premalatha et al. 2014b; Era Consultancy 2006). Being promoted in mountainous
2 global biodiversity hotspots, SHPs have changed the hydrology, water quality and ecology of head-
3 water streams and neighbouring forests significantly. SHPs have created dewatered stretches of
4 stream immediately downstream and introduced sub-daily to sub-weekly hydro-pulses that have
5 transformed the natural dry-season flow regime. Hydrologic and ecological connectivity have been
6 impacted, especially for endemic fish communities and fragmented forests in the Himalayas and
7 Western Ghats biodiversity hotspots in India, and regions in China, and Central America (*medium*
8 *evidence, medium agreement*) (Jumani et al. 2017, 2018; Chhatre and Lakhanpal 2018; Anderson et
9 al. 2006; Grumbine and Pandit 2013). Some regions have opposed SHPs over concerns about impacts
10 on local culture and livelihoods (Jumani et al. 2017, 2018; Chhatre and Lakhanpal 2018).

11 Large scale solar farms that involve large land resources are being installed at a rapid rate. In India,
12 semi-arid and arid regions are targeted for wind and solar farms. India's renewable energy targets
13 are often sited in semi-arid areas which includes the last remaining habitats of the highly
14 endangered Great Indian Bustard (*Ardeotis nigriceps*). Installing solar and wind farms linked to
15 lethal power transmission lines cause mortality of a species whose global population is now reduced
16 to about 150 (Collar et al. 2015). The loss of habitat over the decades has been largely due to
17 agricultural intensification driven by irrigation and bad management in designated reserves (Collar
18 et al. 2015; Ledec, George C.; Rapp, Kennan W.; Aiello 2011) but intrusion of power lines in its
19 last remaining refuges is a major worry for its future persistence (Government of India 2012). In
20 many regions around the world, wind-turbines and solar farms pose a threat to many other species
21 especially predatory birds and insectivorous bats (*medium evidence, medium agreement*) (Thaker,
22 M, Zambre, A. Bhosale 2018) and disrupt habitat connectivity (Northrup and Wittemyer 2013).

23 Additionally, conversion of rivers into waterways has been touted as a fuel-efficient (low carbon
24 emitting) and environment-friendly alternative to surface land transport (IWAI 2016; Dharmadhikary,
25 S., and Sandbhor 2017). India's National Waterways (funded partly by a USD 375 million loan from
26 the World Bank) seeks to cut transportation time and costs and reduce carbon emissions from road
27 transport (Admin 2017). However given the low water levels in India's rivers in the dry-season
28 (due to upstream demands and abstraction) the programme relies on large scale dredging to
29 maintain deep channels. Evidence from elsewhere suggests that dredging could severely impact the
30 water quality, human health and habitat of fish species (Junior et al. 2012; Martins et al. 2012),
31 disrupt artisanal fisheries and potentially cause severe threat to the endangered Ganges River
32 Dolphin (*Platanista gangetica*), India's National Aquatic Animal (Kelkar 2016). The most severe
33 impact of dredging and vessel traffic on this unique species is the disruption through under-water
34 noise of the acoustic signals that the endangered and naturally blind animal relies on for navigation,
35 foraging and communication (*low evidence, medium agreement*) (Dey Mayukh 2018). Off-shore
36 renewable energy projects in coastal zones have been known to have similar impacts on marine fauna
37 (Gill 2005).

38 Policy response to mitigate and reduce the negative impacts of small dams include changes in SHP
39 operations and policies to enable the conservation of river fish diversity. These include mandatory
40 environmental impact assessments, conserving remaining undammed headwater streams in regulated
41 basins, maintaining adequate environmental flows, and implementing other adaptation measures
42 based on experiments with active management of fish communities in impacted zones (Jumani et al.
43 2018). Location of large solar farms needs to be carefully scrutinised (Sindhu et al. 2017). For
44 mitigating negative impacts of power lines associated with solar and wind-farms in bustard habitat,
45 suggested measures include diversion structures to prevent collision, underground cables and
46 avoidance in core wildlife habitat as well as incentives for maintaining low intensity rain-fed
47 agriculture and pasture around existing reserves, and curtailing harmful infrastructure in priority areas
48 (Collar et al. 2015). Mitigation for minimising the ecological impact of Inland Waterways on
49 biodiversity and fisheries is more complicated but may involve improved boat technology to reduce
50 under-water noise, maintaining ecological flows and thus reduced dredging, and avoidance in key
51 habitats (Dey Mayukh 2018).

1 The management of ecological trade-offs of green energy and green infrastructure and transportation
2 projects may be crucial for long-term sustainability and acceptance of emerging low-carbon
3 economies.

5 **7.6. Governance: Governing the land-climate interface**

6 Building on the definition of governance in section 7.1.2, governance situates decision making and
7 selection or calibration of policy instruments within the reality of the multitude of actors operating in
8 respect of land and climate interactions. Governance includes all of the processes, structures, rules and
9 traditions that govern; governance processes may be undertaken by actors including a government,
10 market, organisation, or family (Bevir 2011). Governance processes determine how people in
11 societies make decisions (Patterson et al. 2017) and involve the interactions among formal and
12 informal institutions (see 7.4.1) through which people articulate their interests, exercise their legal
13 rights, meet their legal obligations, and mediate their differences (Plummer and Baird 2013).

14 The act of governance “is a social function centred on steering collective behaviour toward desired
15 outcomes and away from undesirable outcomes” (Young 2017a), here sustainable climate resilient
16 development. This definition of governance allows for it to be decoupled from the more familiar
17 concept of government and studied in the context of complex human-environment relations and
18 environmental and resource regimes (Young 2017a) and used to address the interconnected
19 challenges facing food and agriculture (FAO 2017b). These challenges include assessing, combining,
20 and implementing policy instruments at different governance levels in a mutually reinforcing way,
21 managing trade-offs while capitalising on synergies (see 7.5.6), and employing experimentalist
22 approaches for improved and effective governance (FAO 2017b), here adaptive climate governance
23 (7.6.3). Emphasising governance also represents a shift of traditional resource management (focused
24 on hierarchical state control) towards recognition that political and decision making authority can be
25 exercised through interlinked groups of diverse actors (Kuzdas et al. 2015).

26 This section will start with describing institutions and institutional arrangements (the core of a
27 governance system (Young 2017)) that build adaptive and mitigative capacity, outlining modes, levels
28 and scales of governance for sustainable climate resilient development, describing adaptive climate
29 governance that responds to uncertainty, exploring institutional dimensions of adaptive governance
30 that create an enabling environment for strong institutional capital, discussing land tenure (an
31 important institutional context for effective and appropriate selection of policy instruments), and end
32 with the participation of people in decision making through inclusive governance.

34 **7.6.1. Institutions Building Adaptive and Mitigative Capacity**

35 Institutions are rules and norms held in common by social actors that guide, constrain, and shape
36 human interaction. Institutions can be formal, such as laws, policies, and structured decision making
37 processes (see 7.5.1.1) or informal, such as norms, conventions, and decision making following
38 customary norms and habits (see 7.5.1.2). Organisations – such as parliaments, regulatory agencies,
39 private firms, and community bodies – as well as people, develop and act in response to institutional
40 frameworks and the incentives they frame. “Institutions can guide, constrain, and shape human
41 interaction through direct control, through incentives, and through processes of socialization” (AR5,
42 2014 at p. 1768). Nations with “well developed institutional systems are considered to have greater
43 adaptive capacity,” and better institutional capacity to help deal with risks associated with future
44 climate change (IPCC, 2001 at p. 896). Institutions may also prevent the development of adaptive

1 capacity when they are ‘sticky’ or characterised by strong path dependence (Mahoney 2000) (North
2 1991) and prevent changes that are important to address climate change (see 7.4.9).

3 Formal and informal governance structures are composed of these institutionalised rule systems that
4 determine vulnerability as they influence power relations, risk perceptions and establish the context
5 wherein risk reduction, adaptation and vulnerability are managed (Cardona 2012). Governance
6 institutions determine the management of a community’s assets, the community members’
7 interrelationship, and their relationships with natural resources (Hurlbert and Diaz 2013). Traditional
8 or locally-evolved institutions, backed by cultural norms, can contribute to resilience and adaptive
9 capacity. Anderson et al. suggest these are particularly a feature of dry land societies that are highly
10 prone to environmental risk and uncertainty (Anderson et al. 2010). Concepts of resilience, and
11 specifically the resilience of socio-ecological systems have advanced analysis of adaptive institutions
12 and adaptive governance in relation to climate change and land (Boyd and Folke 2011a). In their
13 characterisation, “resilience is the ability to reorganise following crisis, continuing to learn, evolving
14 with the same identity and function, and also innovating and sowing the seeds for transformation. It is
15 a central concept of adaptive governance” (Boyd and Folke 2012). In the context of complex and
16 multi-scale socio-ecological systems, important features of adaptive institutions that contribute to
17 resilience include the characteristics of an adaptive governance system (see 7.6.6).

18 There is *high confidence* that adaptive institutions include a strong learning dimension and include:

- 19 (1) Institutions advancing the capacity to learn through availability, access to, accumulation of,
20 and interpretation of information (such as drought projections, costing of alternatives land,
21 food, and water strategies). Government supported networks, learning platforms, and
22 facilitated interchange between actors with boundary and bridging organisations, creates the
23 necessary self-organisation to prepare for the unknown. Through transparent, flexible
24 networks, whole sets of complex problems of land, food, and climate can be tackled to
25 develop shared visions and critique land and food management systems assessing gaps and
26 generating solutions;
- 27 (2) Institutions advancing learning by experimentation (in interpretation of information, new
28 ways of governing, and treating policy as an ongoing experiment) through many interrelated
29 decisions, but especially those that connect the social to the ecological and entail anticipatory
30 planning by considering a longer term time frame. Mechanisms to do so include ecological
31 stewardship and rituals and beliefs of indigenous societies that sustain ecosystem services;
- 32 (3) Institutions that decide on pathways to realise system change through cultural, inter and intra
33 organisational collaboration, with a flexible regulatory framework allowing for new cognitive
34 frames of ‘sustainable’ land management and ‘safe’ water supply that open alternative
35 pathways (Karpouzoglou et al. 2016; Bettini et al. 2015; Boyd et al. 2015; Boyd and Folke
36 2011b)) (Boyd and Folke 2012).

37 Shortcomings of resilience theory include limits in relation to its conceptualisation of social change
38 (Cote and Nightingale 2012), its potential to be used as a normative concept implying politically
39 prescriptive policy solutions (Thorén and Olsson 2017; Weichselgartner and Kelman 2015; Milkoreit
40 et al. 2015), its applicability to local needs and experiences (Forsyth 2018), and its potential to hinder
41 evaluation of policy effectiveness (Newton 2016; Olsson et al. 2015b). Regardless, concepts of
42 adaptive institutions building adaptive capacity in complex socio-ecological systems governance
43 have progressed (Karpouzoglou et al. 2016; Dwyer and Hodge 2016) in relation to adaptive
44 governance (Koontz et al. 2015).

45 The study of institutions of governance, levels, modes, and scale of governance, in a multi-level and
46 polycentric fashion is important because of the multi-scale nature of the challenges to resilience,
47 dissemination of ideas, networking and learning.

7.6.2. Integration - Levels, Modes, and Scale of Governance for Sustainable Development

Different types of governance can be distinguished according to intended levels (e.g., local, regional, global), domains (national, international, transnational), modes (market, network, hierarchy), and scales (global regimes to local community groups) (Jordan et al. 2015b). Implementation of climate change adaptation and mitigation has been impeded by institutional barriers including multi-level governance and policy integration issues (Biesbroek et al. 2010). To overcome these barriers, climate governance has evolved significantly beyond the national and multilateral domains that tended to dominate climate efforts and initiatives during the early years of the UNFCCC. The climate challenge has been placed in an “earth system” context, showing the existence of complex interactions and governance requirements across different levels and calling for a radical transformation in governance, rather than minor adjustments (Biermann et al. 2012). Climate governance literature has expanded since AR5 in relation to the sub-national and transnational levels, but all levels and their interconnection is important. Expert thinking has evolved from implementing good governance at high levels of governance (with governments) to a decentred problem solving approach consistent with adaptive governance. This approach involves iterative bottom up and experimental mechanisms that might entail addressing tenure of land or forest management through a territorial approach to development, thereby supporting multi-sectoral governance in local, municipal, and regional contexts (FAO 2017b).

Local action in relation to mitigation and adaptation continues to be important by complementing and advancing global climate policy (Ostrom 2012). Sub-national governance efforts for climate policy, especially at the level of cities and communities, have become significant during the past decades (*medium evidence, medium agreement*) (Castán Broto 2017; Floater et al. 2014; Albers et al. 2015; Archer et al. 2014). A transformation of sorts has been underway through deepening engagement from the private sector and NGOs as well as Government involvement at multiple levels. It is now recognised that business organisations, civil society groups, citizens, and formal governance all have important roles in governance for sustainable development (Kemp et al. 2005).

Transnational governance efforts have increased in number, with application across different economic sectors, geographical regions, civil society groups and non-governmental organisations. When it comes to climate mitigation, transnational mechanisms generally focus on networking and may not necessarily be effective in terms of promoting real emissions reductions (Michaelowa and Michaelowa 2017). However, acceleration in national mitigation measures has been determined to coincide with landmark international events such as the build up to the Copenhagen Climate Conference (Iacobuta et al. 2018). There is a tendency for transnational governance mechanisms to lack monitoring and evaluation procedures (Jordan et al. 2015a).

To address shortcomings of transnational governance, polycentric governance considers the interaction between actors at different levels of governance (local, regional, national, and global) for a more nuanced understanding of the variation in diverse governance outcomes in the management of common-pool resources (such as forests) based on the needs and interests of citizens (Nagendra and Ostrom 2012). A more “polycentric climate governance” system has emerged that incorporates bottom-up initiatives that can support and synergise with national efforts and international regimes (Ostrom 2010). Although it is clear that many more actors and networks are involved, the effectiveness of a more polycentric system remains unclear (Jordan et al. 2015a).

There is *high confidence* that a hybrid form of governance combining the advantages of centralised governance (with coordination, stability, compliance) with those of more horizontal structures (that allow flexibility, autonomy for local decision making, multi-stakeholder engagement, co-management) is required for effective mainstreaming of mitigation and adaptation in sustainable land

1 and forest management (Keenan 2015; Gupta 2014; Williamson and Nelson 2017; Liniger et al.
2 2019). Polycentric institutions self-organise developing collective solutions to local problems as they
3 arise (Koontz et al. 2015). The public sector (governments and administrative systems) are still
4 important in climate change initiatives as these actors retain the political will to implement and make
5 initiatives work (Biesbroek et al. 2018).

6 Sustainable development hinges on the holistic integration of interconnected land and climate issues,
7 sectors, levels of government, and policy instruments (see Policy Coherence 7.4.8), that address the
8 increasing volatility in oscillating systems and weather patterns (Young 2017b; Kemp et al. 2005).
9 Climate adaptation and mitigation goals must be integrated or mainstreamed into existing governance
10 mechanisms around key land use sectors such as forestry and agriculture. In the EU, mitigation has
11 generally been well-mainstreamed in regional policies but not adaptation (Hanger et al. 2015).
12 Climate change adaptation has been impeded by institutional barriers including the inherent
13 challenges of multi-level governance and policy integration (Biesbroek et al. 2010).

14 Integrative polycentric approaches to land use and climate interactions take different forms and
15 operate with different institutions and governance mechanisms. Integrative approaches can provide
16 coordination and linkages to improve effectiveness and efficiency and minimise conflicts (*high*
17 *confidence*). Different types of integration with special relevance for the land-climate interface can be
18 characterised as follows:

- 19 1. Cross-level integration: local and national level efforts must be coordinated with national and
20 regional policies and also be capable of drawing direction and financing from global regimes,
21 thus requiring multi-level governance. Integration of sustainable land management to prevent,
22 reduce, and restore degraded land is advanced with national and subnational policy includes
23 passing the necessary laws establishing frameworks and providing financial incentives.
24 Examples include: integrated territorial planning addressing specific land use decisions; local
25 landscape participatory planning with farmer associations, microenterprises, and local
26 institutions identifying hot spot areas, identifying land use pressures and scaling out
27 sustainable land management response options (Liniger et al. 2019).
- 28 2. Cross-sectoral integration: rather than approach each application or sector (e.g., energy,
29 agriculture, forestry) separately, there is a conscious effort at co-management and
30 coordination in policies and institutions, such as with the energy-water-food nexus (Biggs et
31 al. 2015).
- 32 3. End-use/market integration: often involves exploiting economies of scope across products,
33 supply chains, and infrastructure (Nuhoff-Isakhanyan et al. 2016; Ashkenazy et al. 2017). For
34 instance land-use transport models consider land use, transportation, city planning , and
35 climate mitigation (Ford et al. 2018).
- 36 4. Landscape integration: rather than physical separation of activities (e.g., agriculture, forestry,
37 grazing), uses are spatially integrated by exploiting natural variations while incorporating
38 local and regional economies (Harvey et al. 2014a). In an assessment of 166 initiatives in 16
39 countries, integrated landscape initiatives were found to address the drivers of agriculture,
40 ecosystem conservation, livelihood preservation and institutional coordination. However,
41 such initiatives struggled to move from planning to implementation due to lack of government
42 and financial support and powerful stakeholders sidelining the agenda (Zanzanaini et al.
43 2017). Special care helps ensure initiatives don't exacerbate socio-spatial inequalities across
44 diverse developmental and environmental conditions (Anguelovski et al. 2016b). Integrated
45 land use planning coordinated through multiple government levels balances property rights,
46 wildlife and forest conservation, encroachment of settlements and agricultural areas and can
47 reduce conflict (*high confidence*) (Metternicht 2018). Land use planning can also enhance
48 management of areas prone to natural disasters such as floods and resolve issues of competing
49 land uses and land tenure conflicts (Metternicht 2018).

1
2 Another way to analyse or characterise governance approaches or mechanisms might be according to
3 a temporal scale with respect to relevant events, for example those that may occur gradually vs.
4 abruptly (Cash et al. 2006). Desertification and land degradation are drawn-out processes that occur
5 over many years, whereas extreme events are abrupt and require immediate attention. Similarly, the
6 frequency of events might be of special interest, for example events that occur periodically vs. those
7 that occur infrequently and/or irregularly. In the case of food security abrupt and protracted events of
8 food insecurity might occur. There is a distinction between “hunger months” and longer-term food
9 insecurity. Some indigenous practices already incorporate hunger months whereas structural food
10 deficits have to be addressed differently (Bacon et al. 2014). Governance mechanisms that facilitate
11 rapid response to crises are quite different from those aimed at monitoring slower changes and
12 responding with longer-term measures.

13 **Governance Case Study: Biofuels and bioenergy**

14 New policies and initiatives during the past decade or so have increased support for bioenergy as a
15 non-intermittent (stored) renewable with wide geographic availability that is cost-effective in a range
16 of applications. Significant upscaling of bioenergy requires dedicated (normally land-based) sources
17 in addition to use of wastes and residues. As a result a disadvantage is high land use intensity
18 compared to other renewables (Fritsche et al. 2017b) that in turn place greater demands on
19 governance. Bioenergy, especially traditional fuels currently provides the largest share of renewable
20 energy globally and has a significant role in nearly all climate stabilisation scenarios, although
21 estimates of its potential vary widely (see Cross-Chapter Box 7 on Bioenergy and BECCS in Chapter
22 6). Policies and governance for bioenergy systems and markets must address diverse applications and
23 sectors across levels from local to global; here we briefly review the literature in relation to
24 governance for **modern** bioenergy and biofuels with respect to land and climate impacts whereas
25 **traditional biomass** use (see Glossary) (> 50% of energy used today with greater land use and GHG
26 emissions impacts in low and medium-income countries (Bailis et al. 2015; Masera et al. 2015; Bailis
27 et al. 2017a; Kiruki et al. 2017b)) is addressed elsewhere (see sections 4.5.4 and 7.4.6.4 and Cross-
28 Chapter Box 12 on Traditional Biomass in this chapter). The bioenergy cycle is relevant in accounting
29 for—and attributing—land impacts and GHG emissions (see section 2.5.1.5). Integrated responses
30 across different sectors can help to reduce negative impacts and promote sustainable development
31 opportunities (Table 6.9, Table 6.58). It is *very likely* that bioenergy expansion at a scale that
32 contributes significantly to global climate mitigation efforts (see Cross-Chapter Box 7 on Bioenergy
33 and BECCS in Chapter 6) will result in substantial land use change (Berndes et al. 2015; Popp et al.
34 2014a; Wilson et al. 2014; Behrman et al. 2015; Richards et al. 2017; Harris et al. 2015; Chen et al.
35 2017a). There is *medium evidence and high agreement* that land use change at such scale presents a
36 variety of positive and negative socio-economic and environmental impacts that lead to risks and
37 trade-offs that must be managed or governed across different levels (Pahl-Wostl et al. 2018a; Kurian
38 2017; Franz et al. 2017; Chang et al. 2016; Larcom and van Gevelt 2017; Lubis et al. 2018; Alexander
39 et al. 2015b; Rasul 2014; Bonsch et al. 2016; Karabulut et al. 2018; Mayor et al. 2015). There is
40 *medium evidence and high agreement* that impacts vary considerably with factors such as initial land
41 use type, choice of crops, initial carbon stocks, climatic region, soil types and the management regime
42 and technologies adopted (Qin et al. 2016; Del Grosso et al. 2014; Popp et al. 2017; Davis et al. 2013;
43 Mello et al. 2014; Hudiburg et al. 2015; Carvalho et al. 2016; Silva-Olaya et al. 2017; Whitaker et al.
44 2018; Alexander et al. 2015b);

45 There is *medium evidence and high agreement* that significant socio-economic impacts requiring
46 additional policy responses can occur when agricultural lands and/or food crops are used for
47 bioenergy due to competition between food and fuel (Harvey and Pilgrim 2011; Rosillo Callé and
48 Johnson 2010b), including impacts on food prices (Martin Persson 2015; Roberts and Schlenker 2013;

1 Borychowski and Czyżewski 2015; Koizumi 2014; Muratori et al. 2016; Popp et al. 2014b; Araujo
2 Enciso et al. 2016) and impacts on food security (Popp et al. 2014b; Bailey 2013; Pahl-Wostl et al.
3 2018b; Rulli et al. 2016; Yamagata et al. 2018; Kline et al. 2017; Schröder et al. 2018; Franz et al.
4 2017; Mohr et al. 2016). Additionally crops such as sugar-cane which are water-intensive when used
5 for ethanol production have a trade-off with water and downstream ecosystem services and other
6 crops more important for food security (Rulli et al. 2016; Gheewala et al. 2011). Alongside negative
7 impacts that might fall on urban consumers (who purchase both food and energy), there is *medium*
8 *evidence and medium agreement* that rural producers or farmers can increase income or strengthen
9 livelihoods by diversifying into biofuel crops that have an established market (Maltsoglou et al. 2014;
10 Mudombi et al. 2018a; Gasparatos et al. 2018a,b; von Maltitz et al. 2018; Gasparatos et al. 2018c;
11 Kline et al. 2017; Rodríguez Morales and Rodríguez López 2017; Dale et al. 2015; Lee and Lazarus
12 2013; Rodríguez-Morales 2018). A key governance mechanism that has emerged in response to such
13 concerns, especially during the past decade are standards and certification systems that include food
14 security and land rights in addition to general criteria or indicators related to sustainable use of land
15 and biomass (see section 7.4.6.3 on Standards and Certification). There is *medium evidence and*
16 *medium agreement* that policies promoting use of wastes and residues, the use of non-edible crops
17 and/or reliance on degraded and marginal lands for bioenergy could reduce land competition and
18 associated risk for food security (Manning et al. 2015; Maltsoglou et al. 2014; Zhang et al. 2018a; Gu
19 and Wylie 2017; Kline et al. 2017; Schröder et al. 2018; Suckall et al. 2015; Popp et al. 2014a; Lal
20 2013).

21 There is *medium evidence and high agreement* that good governance, including policy coherence and
22 coordination across the different sectors involved (agriculture, forestry, livestock, energy, transport)
23 (see 7.6.2) can help to reduce the risks and increase the co-benefits of bioenergy expansion
24 (Makkonen et al. 2015; Di Gregorio et al. 2017; Schut et al. 2013; Mukhtarov et al.; Torvanger 2019a;
25 Müller et al. 2015; Nkonya et al. 2015; Johnson and Silveira 2014a; Lundmark et al. 2014; Schultz et
26 al. 2015; Silveira and Johnson 2016; Giessen et al. 2016b; Stattman et al. 2018b; Bennich et al.
27 2017b). There is *medium evidence and high agreement* that the nexus approach can help to address
28 interconnected biomass resource management challenges and entrenched economic interests, as well
29 to leverage synergies in the systemic governance of risk. (Bizikova et al. 2013; Rouillard et al. 2017;
30 Pahl-Wostl 2017a; Lele et al. 2013; Rodríguez Morales and Rodríguez López 2017; Larcom and van
31 Gevelt 2017; Pahl-Wostl et al. 2018a; Rulli et al. 2016; Rasul and Sharma 2016; Weitz et al. 2017b;
32 Karlberg et al. 2015).

33 A key issue for governance of biofuels and bioenergy, as well as land use governance more generally,
34 during the past decade is the need for new governance mechanisms across different levels as land use
35 policies and bioenergy investments are scaled up and result in wider impacts (see section 7.6). There
36 is *low evidence and medium agreement* that hybrid governance mechanisms can promote sustainable
37 bioenergy investments and land use pathways. This hybrid governance can include multi-level,
38 transnational governance, and private-led or partnership-style (polycentric) governance
39 complementing national-level, strong public coordination (government and public
40 administration){7.6.2} (Pahl-Wostl 2017a; Pacheco et al. 2016; Winickoff and Mondou 2017;
41 Nagendra and Ostrom 2012; Jordan et al. 2015a; Djalante et al. 2013; Purkus, Alexandra; Gawel,
42 Erik; Thrän 2012; Purkus et al. 2018; Stattman et al.; Rietig 2018; Cavicchi et al. 2017; Stupak et al.
43 2016; Stupak and Raulund-Rasmussen 2016; Westberg and Johnson 2013; Giessen et al. 2016b;
44 Johnson and Silveira 2014b; Stattman et al. 2018b; Mukhtarov et al.; Torvanger 2019b).

46

Cross-Chapter Box 12: Traditional biomass use: land, climate and development implications

Francis X. Johnson (Sweden), Fahmuddin Agus (Indonesia), Rob Bailis (The United States of America.), Suruchi Bhadwal (India), Annette Cowie (Australia), Tek Sapkota (Nepal)

Introduction and significance

Most biomass used for energy today is in traditional forms (fuelwood, charcoal, agricultural residues) for cooking and heating by some 3 billion persons worldwide (IEA 2017). Traditional biomass has high land and climate impacts, with significant harvesting losses, GHG emissions, soil impacts and high conversion losses (Cutz et al. 2017b; Masera et al. 2015; Ghilardi et al. 2016a; Bailis et al. 2015; Fritsche et al. 2017b; Mudombi et al. 2018b). In addition to these impacts, indoor air pollution from household cooking is a leading cause of mortality in low and medium-income countries and affects especially women and children (Smith et al. 2014a; HEI/IHME 2018; Goldemberg et al. 2018b). In rural areas, the significant time needed for gathering fuelwood imposes further costs on women and children (Njenga and Mendum 2018; Gurung and Oh 2013a; Behera et al. 2015a).

Both agricultural and woody biomass can be upgraded and used sustainably through improved resource management and modern conversion technologies, providing much greater energy output per unit of biomass (Cutz et al. 2017b; Hoffmann et al. 2015a; Gurung and Oh 2013b). More relevant than technical efficiency is the improved quality of energy services: with increasing income levels and/or access to technologies, households transition over time from agricultural residues and fuelwood to charcoal and then to gaseous or liquid fuels and electricity (Leach 1992; Pachauri and Jiang 2008; Goldemberg and Teixeira Coelho 2004; Smeets et al. 2012a). However, most households use multiple stoves and/or fuels at the same time, known as “fuel stacking” for economic flexibility and also for sociocultural reasons (Ruiz-Mercado and Masera 2015a; Cheng and Urpelainen 2014; Takama et al. 2012).

Urban and rural use of traditional biomass

In rural areas, fuelwood is often gathered at no cost to the user and burned directly whereas in urban areas, traditional biomass use may often involve semi-processed fuels, particularly in sub-Saharan Africa where charcoal is the primary urban cooking fuel. Rapid urbanisation and/or commercialisation drives a shift from fuelwood to charcoal, which results in significantly higher wood use (*very high confidence*) due to losses in charcoal supply chains and the tendency to use whole trees for charcoal production (Santos et al. 2017; World Bank. 2009a; Hojas-Gascon et al. 2016a; Smeets et al. 2012b). One study in Myanmar found that charcoal required 23 times the land area of fuelwood (Win et al. 2018). In areas of woody biomass scarcity, animal dung and agricultural residues as well as lower quality wood are often used (Kumar Nath et al. 2013a; Go et al. 2019a; Jagger and Kittner 2017; Behera et al. 2015b). The fraction of woody biomass harvested that is not “demonstrably renewable” is the fraction of non-renewable biomass (fNRB) under UNFCCC accounting; default values for fNRB for least developed countries and small island developing states ranged from 40% to 100% (CDM Executive Board 2012). Uncertainties in woodfuel data, complexities in spatiotemporal woodfuel modelling and rapid forest regrowth in some tropical regions present sources of variation in such estimates, and some fNRB values are *likely* to have been over-estimated (McNicol et al. 2018a; Ghilardi et al. 2016b; Bailis et al. 2017b).

GHG emissions and traditional biomass

Due to overharvesting, incomplete combustion and the effects of short-lived climate pollutants, traditional woodfuels (fuelwood and charcoal) contribute 1.9-2.3% of global GHG emissions; non-renewable biomass is concentrated especially in “hotspot” regions of East Africa and South Asia

(Bailis et al. 2015). The estimate only includes woody biomass and does not account for possible losses in soil carbon or the effects of nutrient losses from use of animal dung, which can be significant in some cases (Duguma et al. 2014a; Achat et al. 2015a; Sánchez et al. 2016). Reducing emissions of black carbon alongside GHG reductions offers immediate health co-benefits (Shindell et al. 2012; Pandey et al. 2017; Weyant et al. 2019a; Sparrevik et al. 2015). Significant GHG emissions reductions, depending on baseline or reference use, can be obtained through fuel-switching to gaseous and liquid fuels, sustainable harvesting of woodfuels, upgrading to efficient stoves, and adopting high-quality processed fuels such as wood pellets (*medium evidence, high agreement*) (Wathore et al. 2017; Jagger and Das 2018; Quinn et al. 2018a; Cutz et al. 2017b; Carter et al. 2018; Bailis et al. 2015; Ghilardi et al. 2018; Weyant et al. 2019b; Hoffmann et al. 2015b).

Land and forest degradation

Land degradation is itself a significant source of GHG emissions and biodiversity loss, with overharvesting of woodfuel as a major cause in some regions and especially in sub-Saharan Africa (Pearson et al. 2017; Joana Specht et al. 2015a; Kiruki et al. 2017b; Ndegwa et al. 2016; McNicol et al. 2018b). Reliance on traditional biomass is quite land-intensive: supplying one household sustainably for a year can require more than half a hectare of land, which, in dryland countries such as Kenya, can result in substantial percentage of total tree cover (Fuso Nerini et al. 2017). In sub-Saharan Africa and in some other regions, land degradation is widely associated with charcoal production (*high confidence*), often in combination with timber harvesting or clearing land for agriculture (Kiruki et al. 2017a; Ndegwa et al. 2016; Hojas-Gascon et al. 2016b). Yet charcoal makes a significant contribution to livelihoods in many areas and thus in spite of the ecological damage, halting charcoal production is difficult due to the lack of alternative livelihoods and/or the affordability of other fuels (Smith et al. 2015; Zulu and Richardson 2013a; Jones et al. 2016a; World Bank. 2009b).

Use of agricultural residues and animal dung for bioenergy

Although agricultural wastes and residues from almost any crop can be used in many cases for bioenergy, excessive removal or reduction of forest (or agricultural) biomass can contribute to a loss of soil carbon, which can also in turn contribute to land degradation (James et al. 2016; Blanco-Canqui and Lal 2009a; Carvalho et al. 2016; Achat et al. 2015b; Stavi and Lal 2015). Removals are limited to levels at which problems of soil erosion, depletion of soil organic matter, soil nutrient depletion and decline in crop yield are effectively mitigated (Ayamga et al. 2015a; Baudron et al. 2014; Blanco-Canqui and Lal 2009b). Application or recycling of residues may in some cases be more valuable for soil improvement (*medium confidence*). Tao et al (2017) used leftover oil palm fruit bunches and demonstrated that application of 30 to 90 t ha⁻¹ empty fruit bunches maintains high palm oil yield with low temporal variability. A wide variety of wastes from palm oil harvesting can be used for bioenergy, including annual crop residues (Go et al. 2019b; Ayamga et al. 2015b; Gardner et al. 2018b).

Animal dung is a low-quality fuel used where woody biomass is scarce, such as in South Asia and some areas of eastern Africa (Duguma et al. 2014b; Behera et al. 2015b; Kumar Nath et al. 2013b). Carbon and nutrient losses can be significant when animal dung is dried and burned as cake, whereas using dung in a biodigester provides high-quality fuel and preserves nutrients in the by-product slurry (Clemens et al. 2018; Gurung and Oh 2013b; Quinn et al. 2018b).

Production and use of biochar

Converting agricultural residues into biochar can also help to reverse trends of soil degradation (see section 4.10.7). The positive effects of using biochar have been demonstrated in terms of soil aggregate improvement, increase of exchangeable cations, cation exchange capacity, available P, soil pH and carbon sequestration as well as increased crop yields (Huang et al. 2018; El-Naggar et al.

2018; Wang et al. 2018; Oladele et al. 2019; Blanco-Canqui and Lal 2009b). The level of biochar effectiveness varies depending on the kind of feedstock, soil properties and rate of application (Shaaban et al. 2018; Pokharel and Chang 2019). In addition to adding value to an energy product, the use of biochar offers a climate-smart approach to address agricultural productivity (Solomon and Lehmann 2017).

Relationship to food security and other SDGs

The population that is food insecure also intersects significantly with those relying heavily on traditional biomass such that poor and vulnerable populations often expend considerable time (gathering fuel) or use a significant share of household income for low quality energy services (Fuso Nerini et al. 2017; McCollum et al. 2018; Rao and Pachauri 2017; Pachauri et al. 2018; Muller and Yan 2018; Takama et al. 2012). Improvements in energy access and reduction or elimination of traditional biomass use thus have benefits across multiple SDGs (*medium evidence, high agreement*) (Masera et al. 2015; Rao and Pachauri 2017; Pachauri et al. 2018; Hoffmann et al. 2017; Jeuland et al. 2015; Takama et al. 2012; Gitau et al. 2019; Quinn et al. 2018b; Ruiz-Mercado and Masera 2015b; Duguma et al. 2014b; Sola et al. 2016b). Improved energy access contributes to adaptive capacity although charcoal production itself can also serve as a diversification or adaptation strategy (Perera et al. 2015; Ochieng et al. 2014; Sumiya 2016; Suckall et al. 2015; Jones et al. 2016b).

Socio-economic choices and shifts

When confronted with the limitations of higher-priced household energy alternatives, climate mitigation policies can result in trade-offs with health, energy access and other SDGs (Cameron et al. 2016; Fuso Nerini et al. 2018). The poorest households have no margin to pay for higher-cost efficient stoves; a focus on product-specific characteristics, user needs and/or making clean options more available would improve the market take-up (*medium confidence*) (Takama et al. 2012; Mudombi et al. 2018c; Khandelwal et al. 2017; Rosenthal et al. 2017; Cundale et al. 2017; Jürisoo et al. 2018). Subsidies for more efficient end-use technologies in combination with promotion of sustainable harvesting techniques would provide the highest emissions reductions while at the same time improving energy services (Cutz et al. 2017a).

Knowledge Gaps

Unlike analyses on modern energy sources, scientific assessments on traditional biomass use are complicated by its informal nature and the difficulty of tracing data and impacts; more systematic analytical efforts are needed to address this research gap (Cerutti et al. 2015). In general, traditional biomass use is associated with poverty. Therefore, efforts to reduce the dependence on fuelwood use are to be conducted in coherence with poverty alleviation (McCollum et al. 2018; Joana Specht et al. 2015b; Zulu and Richardson 2013b). The substantial potential co-benefits suggest that the traditional biomass sector remains under-researched and under-exploited in terms of cost-effective emissions reductions as well as for synergies between climate stabilisation goals and other SDGs.

7.6.3. Adaptive Climate Governance Responding to Uncertainty

In the 1990s, adaptive governance emerged from adaptive management (Holling 1978, 1986), combining resilience and complexity theory, and reflecting the trend of moving from government to governance (Hurlbert 2018b). Adaptive governance builds on multi-level and polycentric governance. Adaptive governance is “a process of resolving trade-offs and charting a course for sustainability” (Boyle, Michelle; Kay, James J.; Pond, 2001 at p. 28) through a range of “political, social, economic and administrative systems that develop, manage and distribute a resource in a manner promoting resilience through collaborative, flexible and learning based issue management across different

1 scales” (Margot A. Hurlbert, 2018 at p. 25). There is *medium evidence and medium agreement* that
2 few alternative governance theories handle processes of change characterised by nonlinear dynamics,
3 threshold effects, cascades and limited predictability; however, the majority of literature relates to the
4 United States or Canada (Karpouzoglou et al. 2016). Combining adaptive governance with other
5 theories has allowed good evaluation of important governance features such as power and politics,
6 inclusion and equity, short term and long term change, and the relationship between public policy and
7 adaptive governance (Karpouzoglou et al. 2016).

8 There is *robust evidence and high agreement* that resource and disaster crises are crises of governance
9 (Pahl-Wostl 2017b; Villagra and Quintana 2017; Gupta et al. 2013b). Adaptive governance of risk has
10 emerged in response to these crises and involves four critical pillars including 1) sustainability as a
11 response to environmental degradation, resource depletion and ecosystem service deterioration; 2)
12 recognition that governance is required as government is unable to resolve key societal and
13 environmental problems including climate change and complex problems; 3) mitigation is a means to
14 reduce vulnerability and avoid exposure; and 4) adaptation responds to changes in environmental
15 conditions (Fra.Paleo 2015).

16 Closely related to (and arguably components of) adaptive governance are adaptive management (see
17 7.5.4) (a regulatory environment that manages ecological system boundaries through hypothesis
18 testing, monitoring, and re-evaluation (Mostert et al. 2007)), adaptive co-management (flexible
19 community based resource management (Plummer and Baird 2013), and anticipatory governance
20 (flexible decision making through the use of scenario planning and reiterative policy review (Boyd et
21 al. 2015). Adaptive governance can be conceptualised as including multilevel governance with a
22 balance between top-down and bottom-up decision making that is performed by many actors
23 (including citizens) in both formal and informal networks, allowing policy measures and governance
24 arrangements to be tailored to local context and matched at the appropriate scale of the problem,
25 allowing for opportunities for experimentation and learning by individuals and social groups
26 (Rouillard et al. 2013; Hurlbert 2018b).

27 There is *high confidence* that anticipation is a key component of adaptive climate governance wherein
28 steering mechanisms in the present are developed to adapt to and/or shape uncertain futures (Vervoort
29 and Gupta 2018; Wiebe et al. 2018; Fuerth 2009). Effecting this anticipatory governance involves
30 simultaneously making short term decisions in the context of longer term policy visioning,
31 anticipating future climate change models and scenarios in order to realise a more sustainable future
32 (Bates and Saint-Pierre 2018; Serrao-Neumann et al. 2013; Boyd et al. 2015). Utilising the decision
33 making tools and practices in 7.5, policy makers operationalise anticipatory governance through a
34 foresight system considering future scenarios and models, a networked system for integrating this
35 knowledge into the policy process, a feedback system using indicators (see 7.5.5) to gauge
36 performance, an open-minded institutional culture allowing for hybrid and polycentric governance
37 (Fuerth and Faber 2013; Fuerth 2009).

38 There is *high confidence* that in order to manage uncertainty, natural resource governance systems
39 need to allow agencies and stakeholders to learn and change over time responding to ecosystem
40 changes and new information with different management strategies and practices that involve
41 experimentation (Camacho 2009; Young 2017b). There is an emerging literature on experimentation
42 in governance surrounding climate change and land use (Kivimaa et al. 2017a) including policies such
43 as REDD+ (Kaisa et al. 2017). Governance experiment literature could be in relation to scaling up
44 policies from the local level for greater application, or downscaling policies addressing broad
45 complex issues such as climate change, or addressing necessary change in social processes across
46 sectors (such as water energy and food) (Laakso et al. 2017). Successful development of new policy
47 instruments occurred in a governance experiment relating to coastal policy adapting to rising sea
48 levels and extreme weather events through planned retreat (Rocle and Salles 2018). Experiments in

1 emission trading between 1968 and 2000 in the United States of America helped to realise specific
2 models of governance and material practices through mutually supportive lab experiments and field
3 application that advanced collective knowledge (Voß and Simons 2018).

4 There is *high confidence* that a sustainable land management plan is dynamic and adaptive over time
5 to (unforeseen) future conditions by monitoring indicators as early warnings or signals of tipping
6 points initiating a process of change in policy pathway before a harmful threshold is reached
7 (Stephens et al. 2018, 2017; Haasnoot et al. 2013; Bloemen et al. 2018)(see 7.5.2.2). This process has
8 been applied in relation to coastal sea level rise starting with low risk, low cost measures and working
9 up to measures requiring greater investment after review and reevaluation (Barnett et al. 2014). A
10 first measure was stringent controls of new development, graduating to managed relocation of low
11 lying critical infrastructure, and eventually movement of habitable dwellings to more elevated parts
12 of town, as flooding and inundation triggers are experienced (Haasnoot et al. 2018; Lawrence et al.
13 2018; Barnett et al. 2014; Stephens et al. 2018). Nanda et al. (2018) apply the concept to a wetland in
14 Australia to identify a mix of short and long-term decisions, and Prober et al. (2017) develop
15 adaptation pathways for agricultural landscapes, also in Australia. Both studies identify that longer-
16 term decisions may involve a considerable change to institutional arrangements at different scales.
17 Viewing climate mitigation as a series of connected decisions over a long time period and not an
18 isolated decision, reduces the fragmentation and uncertainty endemic of models and effectiveness of
19 policy measures (Roelich and Gieseckam 2019).

20 There is *medium evidence and high agreement* that participatory processes in adaptive governance
21 within and across policy regimes overcome limitations of polycentric governance allowing priorities
22 to be set in sustainable development through rural land management and integrated water resource
23 management (Rouillard et al. 2013). Adaptive governance addresses large uncertainties and their
24 social amplification through differing perceptions of risk (Kasperson 2012; Fra.Paleo 2015) offering
25 an approach to co-evolve with risk by implementing policy mixes and assessing effectiveness in an
26 ongoing process, making mid-point corrections when necessary (Fra.Paleo 2015). In respect of
27 climate adaptation to coastal and riverine land erosion due to extreme weather events impacting
28 communities, adaptive governance offers the capacity to monitor local socio-economic processes and
29 implement dynamic locally informed institutional responses. In Alaska adaptive governance
30 responded to the dynamic risk of extreme weather events and issue of climate migration by providing
31 a continuum of policy from protection in place to community relocation, integrating across levels and
32 actors in a more effective and less costly response option than other governance systems (Bronen and
33 Chapin 2013). In comparison to other governance initiatives of ecosystem management aimed at
34 conservation and sustainable use of natural capital, adaptive governance has visible effects on natural
35 capital by monitoring, communicating and responding to ecosystem-wide changes at the landscape
36 level (Schultz et al. 2015). Adaptive governance can be applied to manage drought assistance as a
37 common property resource managing complex, interacting goals to create innovative policy options,
38 facilitated through nested and polycentric systems of governance effected by areas of natural resource
39 management including landscape care and watershed or catchment management groups (Nelson et al.
40 2008).

41 There is *medium evidence and high agreement* that transformational change is a necessary societal
42 response option to manage climate risks which is uniquely characterised by the depth of change
43 needed to reframe problems and change dominant mindsets, the scope of change needed (that is larger
44 than just a few people) and the speed of change required to reduce emissions (O' Brien et al. 2012;
45 Termeer et al. 2017). Transformation of governance occurs with changes in values to reflect an
46 understanding that the environmental crisis occurs in the context of our relation with the earth
47 (Hordijk et al. 2014; Pelling 2010). Transformation can happen by intervention strategies that enable
48 small in-depth wins, amplify these small wins through integration into existing practices, and unblock

1 stagnations (locked in structures) preventing transformation by confronting social and cognitive
2 fixations with counterintuitive interventions (Termeer et al. 2017). Iterative consideration of issues
3 and reformulation of policy instruments and response options facilitates transformation by allowing
4 experimentation (Monkelbaan 2019).

6 **Box 7.2 Adaptive Governance and interlinkages of food, fiber, water, energy and land**

7 Emerging literature and case studies recognise the connectedness of the environment and human
8 activities and the interrelationships of multiple resource-use practices in an attempt to understand
9 synergies and trade-offs (Albrecht et al. 2018). Sustainable adaptation - or actions contributing to
10 environmentally and socially sustainable development pathways (Eriksen et al. 2011) - requires
11 consideration of the interlinkage of different sectors (Rasul and Sharma 2016). Integrating
12 considerations can address sustainability (Hoff 2011) showing promise (Allan et al. 2015) for
13 effective adaptation to climate impacts in many drylands (Rasul and Sharma 2016).

14 Case studies of integrated water resources management (IWRM), landscape and ecosystem based
15 approaches illustrate important dimensions of institutions, institutional coordination, resource
16 coupling and local and global connections (Scott et al. 2011). Integrated governance, policy
17 coherence, and use of multi-functional systems are required to advance synergies across land, water,
18 energy and food sectors (Liu et al. 2017).

19 **Case Study: Flood and Food Security**

20 Between 2003–2013 floods were the most impacting natural disaster on crop production (FAO 2015b)
21 (albeit in certain contexts such riverine ecosystems and flood plain communities floods can be
22 beneficial).

23 In developing countries flood jeopardises primary access to food and impacts livelihoods. In
24 Bangladesh the 2007 flood reduced average consumption by 103Kcal/cap/day (worsening the existing
25 19.4% calories deficit) and in Pakistan the 2010 flood resulted in a loss of 205 Kcal/cap/day (or 8.5%
26 of the Pakistan average food supply). The Pakistan 2010 flood affected over 4.5 million workers, two
27 thirds employed in agriculture; 79% of farms lost greater than one half of their expected income
28 (Pacetti et al. 2017).

29 Policy instruments and response respond to the sequential and cascading impacts of flood. In a
30 Malawi study, flood impacts cascaded through labour, trade and transfer systems. First a harvest
31 failure occurred, followed by the decline of employment opportunities and reduction in real wages,
32 followed by a market failure or decline in trade, ultimately followed by a failure in informal safety
33 nets (Devereux 2007). Planned policy responses include those that address the sequential nature of
34 the cascading impacts starting with ‘productivity-enhancing safety nets’ addressing harvest failure,
35 then public works programmes addressing the decline in employment opportunities, followed by food
36 price subsidies to address the market failure, and finally food aid to address the failure of informal
37 safety nets (Devereux 2007). In another example in East Africa range lands, flood halted livestock
38 sales, food prices fell, and grain production ceased. Local food shortages couldn’t be supplemented
39 with imports due to destruction of transport links, and pastoral incomes were inadequate to purchase
40 food. Livestock diseases became rampant and eventually food shortages led to escalating prices. Due
41 to the contextual nature and timing of events, policy response initially addressed mobility and
42 resource access, and eventually longer term issues such as livestock disease (Little et al. 2001).

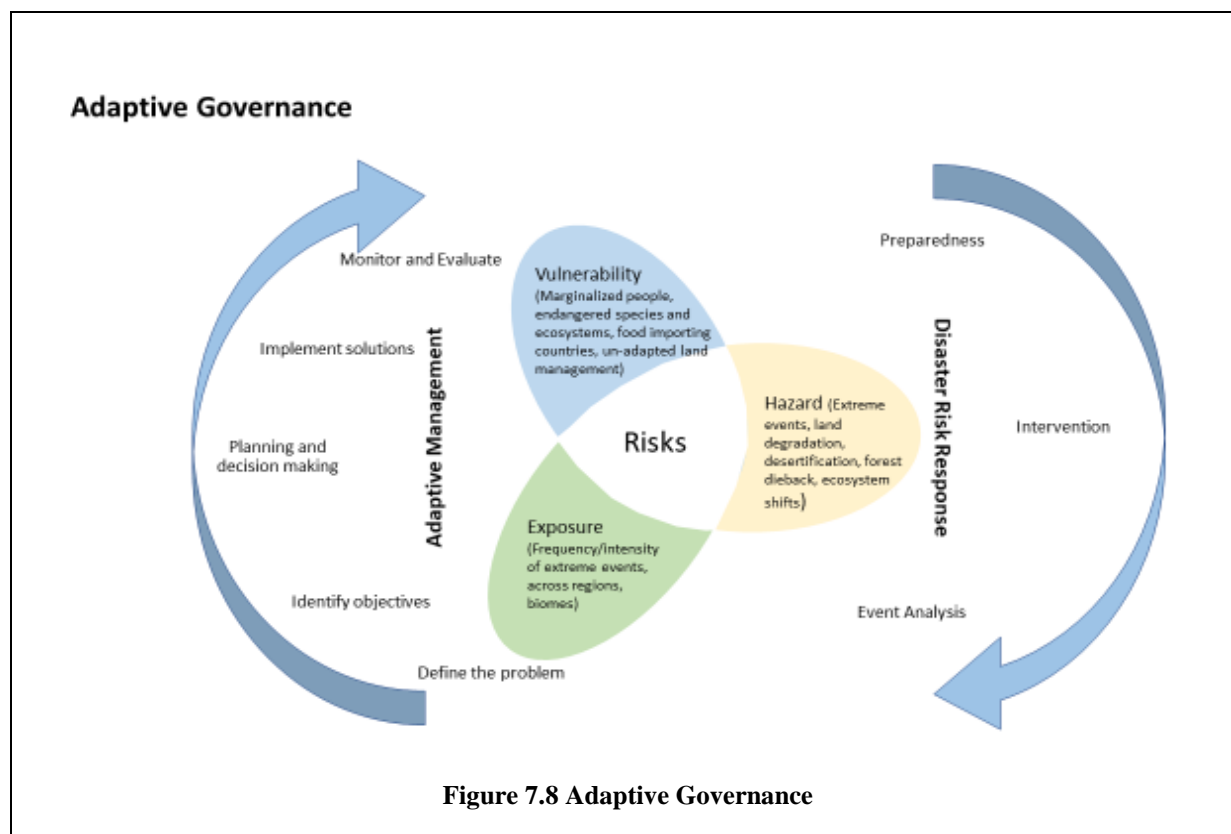

43 In North America floods are often described in terms of costs. For instance, the 1997 Red River
44 Basin flood cost Manitoba, Canada \$1 billion US and the United States of America, \$4 billion US in
45 terms of impact on agriculture and food production (Adaptation to Climate Change Team 2013). In
46 Canada floods accounted for 82% of disaster financial assistance spent from 2005–2014 (Public

1 Safety Canada 2017) and this cost may increase in the future. Future climate change may result in a
2 six foot rise in sea level by 2100 costing from USD 507 to 882 billion, affecting 300 American cities
3 (losing one half of their homes) and the wholesale loss of 36 cities (Lemann 2018).

4 Policy measures are important as an increasingly warming world may make post disaster assistance
5 and insurance increasingly unaffordable (Surminski et al. 2016). Historic legal mechanisms for
6 retreating from low lying and coastal areas have failed to encourage relocation of people out of flood
7 plains and areas of high risk (Stoa 2015). In some places cheap flood insurance and massive aid
8 programs have encouraged the populating of low-lying flood prone and coastal areas (Lemann 2018).
9 Although the state makes disaster assistance payments, it is local governments that determine
10 vulnerability through flood zone mapping, restrictions from building in flood zones, building
11 requirements (Stoa 2015), and integrated planning for flood. A comprehensive policy mix (see 7.4.8)
12 (implemented through adaptive management as illustrated on Figure 7.6) reduces vulnerability
13 (Hurlbert 2018b) (Hurlbert 2018a). Policy mixes that allow people to respond to disasters include
14 bankruptcy, insolvency rules, house protection from creditors, income minimums, and basic
15 agricultural implement protection laws. The portfolio of policies allows people to recover, and if
16 necessary migrate to other areas and occupations (Hurlbert 2018b).

17 At the international level, reactionary disaster response has evolved to proactive risk management that
18 combines adaptation and mitigation responses to ensure effective risk response, build resilient systems
19 and solve issues of structural social inequality (Innocenti and Albrito 2011). Advance measures of
20 preparedness are the main instruments to reduce fatalities and limit damage, as illustrated on the
21 figure below. The Sendai Declaration and Framework for Disaster Risk Reduction 2015-2030, is an
22 action plan to reduce mortality, the numbers of affected people and economic losses with four
23 priorities - understanding disaster risk, strengthening its governance to enhance the ability to manage
24 disaster risk, investing in resilience, and enhancing disaster preparedness. There is *medium evidence*
25 *and high agreement* that the Sendai Framework significantly refers to adaptive governance and could
26 be a window of opportunity to transform disaster risk reduction to address the causes of vulnerability
27 (Munene et al. 2018). Addressing disasters increasingly requires individual, household, community
28 and national planning and commitment to a new path of resilience and shared responsibility through
29 whole community engagement and linking private and public infrastructure interests (Rouillard et al.
30 2013). It is recommended that a vision and overarching framework of governance be adopted to allow
31 participation and coordination by government, nongovernmental organisations, researchers and the
32 private sector, individuals in the neighbourhood community. Disaster risk response is enhanced with
33 complementary structural and non-structural measures implemented together with measurable
34 scorecard indicators (Chen 2011).

1

2

3

Figure 7.8 Adaptive Governance

4 Adaptive management identifies and responds to exposure and vulnerability to land and climate
 5 change impacts by identifying problems and objectives, making decisions in relation to response
 6 options and instruments advancing response options in the context of uncertainty. These decisions are
 7 continuously monitored, evaluated and adjusted to changing conditions. Similarly disaster risk
 8 management responds to hazards through preparation, prevention, response, analysis, and
 9 reconstruction in an iterative process.

10

11 **7.6.4. Participation**

12 It is recognised that more benefits are derived when citizens actively participate in land and climate
 13 decision making, conservation, and policy formation (*high confidence*) (Jansujwicz et al. 2013)
 14 (Coenen and Coenen 2009; Hurlbert and Gupta 2015). Local leaders supported by strong laws,
 15 institutions, collaborative platforms, are able to draw on local knowledge, challenge external
 16 scientists, and find transparent and effective solutions for climate and land conflicts (Couvet and
 17 Prevot 2015; Johnson et al. 2017). Meaningful participation is more than providing
 18 technical/scientific information to citizens in order to accept decisions already made, but allows
 19 citizens to deliberate about climate change impacts to determine shared responsibilities creating
 20 genuine opportunity to construct, discuss, and promote alternatives (*high confidence*)(Lee et al. 2013;
 21 Armeni 2016; Pieraccini 2015)(Serrao-Neumann et al. 2015b; Armeni 2016). Participation is an
 22 emerging quality of collective-action and social-learning processes (see below) (Castella et al. 2014)
 23 when barriers for meaningful participation are surpassed (Clemens et al. 2015). The absence of
 24 systematic leadership, the lack of consensus on the place of direct citizen participation, and the limited
 25 scope and powers of participatory innovations limits the utility of participation (Fung 2015).

26 Multiple methods of participation exist, including multi-stakeholder forums, participatory scenario
 27 analyses, public forums and citizen juries (Coenen and Coenen 2009). No one method is superior, but
 28 each method must be tailored for local context (*high confidence*)(Blue and Medlock 2014; Voß and

1 Amelung 2016). Strategic innovation in developing policy initiatives requires a strategic adaptation
2 framework involving pluralistic and adaptive processes and use of boundary organisations (Head
3 2014).

4 The framing of a land and climate issue can influence the manner of public engagement (Hurlbert and
5 Gupta 2015) and studies have found local frames of climate change are particularly important
6 (Hornsey et al. 2016; Spence et al. 2012), emphasising diversity of perceptions to adaptation and
7 mitigation options (Capstick et al. 2015) (although Singh and Swanson (2017) found little evidence
8 framing impacted the perceived importance of climate change).

9 Recognition and use of indigenous and local knowledge (ILK) is an important element of
10 participatory approaches of various kinds. ILK can be used in decision-making on climate change
11 adaptation, Sustainable Land Management and food security at various scales and levels and is
12 important for long-term sustainability (*high confidence*). Cross-Chapter Box 13 discusses definitional
13 issues associated with ILK, evidence of its usefulness in responses to land-climate challenges,
14 constraints on its use, and possibilities for its incorporation in decision-making.
15

16 **Cross-Chapter Box 13: Indigenous and Local Knowledge**

17 John Morton (United Kingdom), Fatima Denton (The Gambia), James Ford (United Kingdom), Joyce
18 Kimutai (Kenya), Pamela McElwee (The United States of America), Marta Rivera Ferre (Spain),
19 Lindsay Stringer (United Kingdom)
20

21 Indigenous and local knowledge (ILK) can play a key role in climate change adaptation (*high*
22 *confidence*) (Mapfumo et al. 2017; Nyong et al. 2007b; Green and Raygorodetsky 2010; Speranza et
23 al. 2010; Alexander et al. 2011a; Leonard et al. 2013; Nakashima et al. 2013; Tschakert 2007). The
24 Summary for Policy-Makers of the Working Group II Contribution to the IPCC’s Fifth Assessment
25 Report (IPCC 2014b, p. 26) states that “Indigenous, local, and traditional knowledge systems and
26 practices, including indigenous peoples’ holistic view of community and environment, are a major
27 resource for adapting to climate change, but these have not been used consistently in existing
28 adaptation efforts. Integrating such forms of knowledge with existing practices increases the
29 effectiveness of adaptation” (see also Ford et al. 2016). The Special Report on Global Warming of
30 1.5 °C (IPCC 2018e; de Coninck et al. 2018) confirms the effectiveness and potential feasibility of
31 adaptation options based on ILK but also raises concerns that such knowledge systems are being
32 threatened by multiple socio-economic and environmental drivers (*high confidence*). The
33 Intergovernmental Platform on Biodiversity and Ecosystem Services (IPBES) Land Degradation and
34 Restoration Assessment (IPBES 2018) finds the same– that ILK can support adaptation to land
35 degradation but is threatened.
36

37 A variety of terminology has been used to describe indigenous and local knowledge: “Indigenous
38 knowledge”, “local knowledge”, “traditional knowledge”, “traditional ecological knowledge” and
39 other terms are used in overlapping and often inconsistent ways (Naess 2013). The Special Report on
40 Global Warming of 1.5°C (IPCC 2018a) reserves “indigenous knowledge” for culturally distinctive
41 ways of knowing associated with “societies with long histories of interaction with their natural
42 surroundings”, while using “local knowledge” for “understandings and skills developed by
43 individuals and populations, specific to the places where they live”, but not all research studies
44 observe this distinction. This Special Report generally uses “indigenous and local knowledge” (ILK)
45 as a combined term for these forms of knowledge, but in some sections the terminology used follows
46 that from the research literature assessed.
47

48 In contrast to scientific knowledge, ILK is context-specific, collective, transmitted informally, and is
49 multi-functional (Mistry and Berardi 2016; Naess 2013; Janif et al. 2016). Persson et al. (2018)
50 characterise ILK as “practical experience”, as locally-held knowledges are acquired through processes
51 of experience and interaction with the surrounding physical world. ILK is embedded in local

1 institutions (Naess 2013) and in cultural aspects of landscape and food systems (Fuller and Qingwen
2 2013; Koohafkan and Altieri 2011). ILK can encompass such diverse content as factual information
3 about the environment; guidance on rights and management; value statements about interactions with
4 others; and cosmologies and worldviews that influence how information is perceived and acted upon,
5 among other topics (Spoon 2014; Usher 2000).

6
7 This Cross-Chapter Box assesses evidence for the positive role of ILK in understanding climate
8 change and other environmental processes, and in managing land sustainably in the face of climate
9 change, desertification, land degradation and food insecurity. It also assesses constraints on and
10 threats to the use of ILK in these challenges, and processes by which ILK can be incorporated in
11 decision-making and governance processes.

12 13 *ILK in understanding and responding to climate change impacts*

14
15 ILK can play a role in understanding climate change and other environmental processes, particularly
16 where formal data collection is sparse (Alexander et al. 2011a; Schick et al. 2018), and can contribute
17 to accurate predictions of impending environmental change (Green and Raygorodetsky 2010; Orlove
18 et al. 2010) (medium confidence). Both at global level (Alexander et al. 2011a; Green and
19 Raygorodetsky 2010), and local level (Speranza et al. 2010; Ayanlade et al. 2017), strong correlations
20 between local perceptions of climate change and meteorological data have been shown, as calendars,
21 almanacs, and other seasonal and interannual systems knowledge embedded in ILK hold information
22 about environmental baselines (Orlove et al. 2010; Cochran et al. 2016).

23
24 ILK is strongly associated with sustainable management of natural resources, including land, and with
25 autonomous adaptation to climate variability and change, while also serving as a resource for
26 externally-facilitated adaptation (Stringer et al. 2009). For example, women’s traditional knowledge
27 adds value to a society’s knowledge base and supports climate change adaptation practices (Lane and
28 McNaught 2009). In dryland environments, populations have historically demonstrated remarkable
29 resilience and innovation to cope with high climatic variability, manage dynamic interactions between
30 local communities and ecosystems, and sustain livelihoods (Safriel and Adeel 2008; Davies 2017).
31 There is high confidence that pastoralists have created formal and informal institutions based on ILK
32 for regulating grazing, collection and cutting of herbs and wood, and use of forests across the Middle
33 East and North Africa (Louhaichi and Tastad 2010; Domínguez 2014; Auclair et al. 2011), Mongolia
34 (Fernandez-Gimenez 2000), The Horn of Africa (Oba 2013) and the Sahel (Krätli and Schareika
35 2010). Herders in both the Horn of Africa and the Sahel have developed complex livestock breeding
36 and selection systems for their dryland environment (Krätli 2008; Fre 2018). Numerous traditional
37 water harvesting techniques are used across the drylands to adapt to climate variability: planting pits
38 (“zai”, “ngoro”) and micro-basins and contouring hill slopes and terracing (Biazin et al. 2012),
39 alongside the traditional “ndiva” water harvesting system in Tanzania to capture runoff in community-
40 managed micro-dams for small-scale irrigation (Enfors and Gordon 2008).

41
42 Across diverse agro-ecological systems, ILK is the basis for traditional practices to manage the
43 landscape and sustain food production, while delivering co-benefits in the form of biodiversity and
44 ecosystem resilience at a landscape scale (high confidence). Flexibility and adaptiveness are
45 hallmarks of such systems (Richards 1985; Biggs et al. 2013), and documented examples include:
46 traditional integrated watershed management in the Philippines (Camacho et al. 2016); widespread
47 use of terracing with benefits in cases of both intensifying and decreasing rainfall (Arnáez et al. 2015;
48 Chen et al. 2017b) and management of water harvesting and local irrigation systems in the Indo-
49 Gangetic Plain (Rivera-Ferre et al. 2016). Rice cultivation in East Borneo is sustained by traditional
50 forms of shifting cultivation, often involving intercropping of rice with bananas, cassava and other
51 food crops (Siahaya et al. 2016), although the use of fire in land clearance implies trade-offs for
52 climate change mitigation which have been sparsely assessed. Indigenous practices for enhanced soil
53 fertility have been documented among South Asian farmers (Chandra et al. 2011; Dey and Sarkar
54 2011) and among Mayan farmers where management of carbon has positive impacts on mitigation
55 (Falkowski et al. 2016). Korean traditional groves or “bibosoop” have been shown to reduce wind

1 speed and evaporation in agricultural landscapes (Koh et al. 2010). Particularly in the context of
2 changing climates, agriculture based on ILK that focuses on biodiversification, soil management, and
3 sustainable water harvesting holds promise for long-term resilience (Altieri and Nicholls 2017) and
4 rehabilitation of degraded land (Maikhuri et al. 1997). ILK is also important in other forms of
5 ecosystem management, such as forests and wetlands, which may be conserved by efforts such as
6 sacred sites (Ens et al. 2015; Pungetti et al. 2012) and ILK can play an important role in ecological
7 restoration efforts, including for carbon sinks, through knowledge surrounding species selection and
8 understanding of ecosystem processes, like fire (Kimmerer 2000).

9 10 *Constraints on the use of ILK*

11
12 Use of ILK as a resource in responding to climate change can be constrained in at least three ways
13 (high confidence). Firstly the rate of climate change and the scale of its impacts may render
14 incremental adaptation based on the ILK of smallholders and others, less relevant and less effective
15 (Lane and McNaught 2009; Orłowsky and Seneviratne 2012; Huang et al. 2016; Morton 2017).
16 Secondly, maintenance and transmission of ILK across generations may be disrupted by e.g.: formal
17 education, missionary activity, livelihood diversification away from agriculture, and a general
18 perception that ILK is outdated and unfavourably contrasted with scientific knowledge (Speranza et
19 al. 2010), and by HIV-related mortality (White and Morton 2005). Urbanisation can erode ILK,
20 although ILK is constantly evolving, and becoming integrated into urban environments (Júnior et al.
21 2016; Oteros-Rozas et al. 2013; van Andel and Carvalheiro 2013). Thirdly, ILK holders are
22 experiencing difficulty in using ILK due to loss of access to resources, such as through large-scale
23 land acquisition (Siahaya et al. 2016; Speranza et al. 2010; de Coninck et al. 2018) and the increasing
24 globalisation of food systems and integration into global market economy also threatens to erode ILK
25 (Gómez-Baggethun et al. 2010; Oteros-Rozas et al. 2013; McCarter et al. 2014). The potential role
26 that ILK can play in adaptation at the local level depends on the configuration of a policy-institutions-
27 knowledge nexus (Stringer et al. 2018), which includes power relations across levels and interactions
28 with government strategies (Alexander et al. 2011b; Naess 2013).

29 30 *Incorporation of ILK in decision-making*

31
32 ILK can be used in decision-making on climate change adaptation, Sustainable Land Management
33 and food security at various scales and levels and is important for long-term sustainability (high
34 confidence). Respect for ILK is both a requirement and an entry strategy for participatory climate
35 action planning and effective communication of climate action strategies (Nyong et al. 2007b). The
36 nature, source, and mode of knowledge generation are critical to ensure that sustainable solutions are
37 community-owned and fully integrated within the local context (Mistry and Berardi 2016). Integrating
38 ILK with scientific information is a prerequisite for such community-owned solutions. Scientists can
39 engage farmers as experts in processes of knowledge co-production (Oliver et al. 2012), helping to
40 introduce, implement, adapt and promote locally appropriate responses (Schwilch et al. 2011).
41 Specific approaches to decision-making that aim to integrate indigenous and local knowledge include
42 some versions of decision support systems (Jones et al. 2014) as well as citizen science and
43 participatory modelling (Tengö et al. 2014).

44
45 ILK can be deployed in the practice of climate governance especially at the local level where actions
46 are informed by the principles of decentralisation and autonomy (Chanza and de Wit 2016;
47 Harmsworth and Awatere 2013). International environmental agreements also are increasingly
48 including attention to ILK and diverse cultural perspectives, for reasons of social justice and inclusive
49 decision-making (Brondizio and Tourneau 2016). However, the context-specific, and dynamic nature
50 of ILK and its embeddedness in local institutions and power relations needs consideration (Naess
51 2013). It is also important to take a gendered approach so as not to further marginalise certain
52 knowledge, as men and women hold different knowledge, expertise and transmission patterns (Díaz-
53 Reviriego et al. 2017).

1 **Citizen Science**

2 Citizen science is a democratic approach to science involving citizens in collecting, classifying, and
3 interpreting data to influence policy and assist decision processes, including issues relevant to the
4 environment (Kullenberg and Kasperowski 2016). It has flourished in recent years due to easily
5 available technical tools for collecting and disseminating information (e.g., cell phone-based apps,
6 cloud-based services, ground sensors, drone imagery, and others), recognition of its free source of
7 labour, and requirements of funding agencies for project related outreach (Silvertown 2009). There is
8 significant potential for combining citizen science and participatory modelling to obtain favourable
9 outcomes and improve environmental decision making (*medium confidence*) (Gray et al. 2017).
10 Citizen participation in land use simulation integrates stakeholders' preferences through the
11 generation of parameters in analytical and discursive approaches (Hewitt et al. 2014), and thereby
12 supports the translation of narrative scenarios to quantitative outputs (Mallampalli et al. 2016),
13 supports the development of digital tools to be used in co-designing decision making participatory
14 structures (Bommel et al. 2014), and supports the use of games to understand the preferences of local
15 decision making when exploring various balanced policies about risks (Adam et al. 2016).

16 There is *medium confidence* that citizen science improves sustainable land management through
17 mediating and facilitating landscape conservation decision making and planning, as well as boosting
18 environmental awareness and advocacy (Lange and Hehl-Lange 2011; Bonsu et al. 2017; Graham et
19 al. 2015) (Bonsu et al. 2017) (Lange and Hehl-Lange 2011) (Sayer, J. Margules, C., Boedhihartono
20 2015) (McKinley et al. 2017) (Johnson et al. 2017, 2014) (Gray et al. 2017). One study found limited
21 evidence of direct conservation impact (Ballard et al. 2017) and most of the cases derive from rich
22 industrialised countries (Loos et al. 2015). There are many practical challenges to the concept of
23 citizen science at the local level, which include differing methods and the lack of universal
24 implementation framework (Conrad and Hilchey 2011; Jalbert and Kinchy 2016; Stone et al. 2014).
25 Uncertainty related to citizen science needs to be recognised and managed (Swanson et al. 2016; Bird
26 et al. 2014; Lin et al. 2015) and citizen science projects around the world need better coordination to
27 understand significant issues, such as climate change (Bonney et al. 2014).
28

29 **Participation, Collective Action, and Social Learning**

30 As land and climate issues cannot be solved by one individual, a diverse collective action issue exists
31 for land use policies and planning practices (Moroni 2018) at local, national, and regional levels.
32 Collective action involves individuals and communities in land planning processes in order to
33 determine successful climate adaptation and mitigation (Nkoana et al. 2017) (Liu and Ravenscroft
34 2017) (Nieto-Romero et al. 2016; Nikolakis et al. 2016), or as Sarzynski (2015) finds, a community
35 'pulling together' to solve common adaptation and land planning issues.

36 Collective action offers solutions for emerging land and climate change risks, including strategies
37 that target maintenance or change of land use practices, increase livelihood security, risk share
38 through pooling, and sometimes also aim to promote social and economic goals such as reducing
39 poverty (Samaddar et al. 2015)(Andersson and Gabrielsson 2012). Collective action has resulted in
40 the successful implementation of national-level land transfer policies (Liu and Ravenscroft 2017),
41 rural development and land sparing (Jelsma et al. 2017), and the development of tools to identify
42 shared objectives, trade-offs and barriers to land management (Nieto-Romero et al. 2016; Nikolakis et
43 al. 2016). Collective action can also produce mutually binding agreements, government regulation,
44 privatisation, and incentive systems (IPCC 2014c).

45 Successful collective action requires understanding and implementation of factors that determine
46 successful participation in climate adaptation and mitigation (Nkoana et al. 2017). These include
47 ownership, empowerment or self-reliance, time effectiveness, economic and behavioural interests,
48 livelihood security, and the requirement for plan implementation (Samaddar et al. 2015; Djurfeldt et
49 al. 2018) (Sánchez and Maseda 2016). In a UK study, dynamic trust relations among members
50 around specific issues, determined the potential of agri-environmental schemes to offer landscape-

1 scale environmental protection (Riley et al. 2018). Collective action is context specific and rarely
2 scaled up or replicated in other places (Samaddar et al. 2015).

3 Collective action in land use policy has been shown to be more effective when implemented as
4 bundles of actions rather than as single-issue actions. For example, land tenure, food security, and
5 market access can mutually reinforce each other when they are interconnected (Corsi et al. 2017). For
6 example, (Liu and Ravenscroft 2017) found that financial incentives embedded in collective forest
7 reforms in China have increased forest land and labour inputs in forestry.

8 A product of participation, equally important in practical terms, is social learning (*high confidence*)
9 (Reed et al. 2010) (Dryzek and Pickering 2017) (Gupta 2014), which is learning in and with social
10 groups through interaction (Argyris 1999) including collaboration and organisation which occurs in
11 networks of interdependent stakeholders (Mostert et al. 2007). Social learning is defined as a change
12 in understanding measured by a change in behaviour, and perhaps worldview, by individuals and
13 wider social units, communities of practice and social networks (Reed et al. 2010) (Gupta 2014).
14 Social learning is an important factor contributing to long-term climate adaptation whereby
15 individuals and organisations engage in a multi-step social process, managing different framings of
16 issues while raising awareness of climate and land risks and opportunities, exploring policy options
17 and institutionalising new rights, responsibilities, feedback and learning processes (Tàbara et al.
18 2010). It is important for engaging with uncertainty (Newig et al. 2010) and addressing the increasing
19 unequal geography of food security (Sonnino et al. 2014).

20 Social learning is achieved through reflexivity or the ability of a social structure, process, or set of
21 ideas to reconfigure itself after reflection on performance though open-minded people interacting
22 iteratively to produce reasonable and well-informed opinions (Dryzek and Pickering 2017). These
23 processes develop through skilled facilitation attending to social difference and power resulting in a
24 shared view of how change might happen (Harvey et al. 2012; Ensor and Harvey 2015). When
25 combined with collective action, social learning can make transformative change measured by a
26 change in worldviews (beliefs about the world and reality) and understanding of power dynamics
27 (Gupta 2014) (Bamberg et al. 2015).

28 **7.6.5. Land Tenure**

29 Land tenure, defined as “the terms under which land and natural resources are held by individuals,
30 households or social groups”, is a key dimension in any discussion of land-climate interactions,
31 including the prospects for both adaptation and land-based mitigation, and possible impacts on tenure
32 and thus land security of both climate change and climate action (Quan and Dyer 2008) (*medium*
33 *evidence, high agreement*).

34 Discussion of land tenure in the context of land-climate interactions in developing countries needs to
35 consider the prevalence of informal, customary and modified customary systems of land tenure:
36 estimates range widely, but perhaps as much as 65% of the world’s total land area is managed under
37 some form of these local, customary or communal tenure systems, and only a small fraction of this
38 (around 15%) is formally recognised by governments (Rights and Resources Initiative 2015a). These
39 customary land rights can extend across many categories of land, but are difficult to assess properly
40 due to poor reporting, lack of legal recognition, and lack of access to reporting systems by indigenous
41 and rural peoples (Rights and Resources Initiative 2018a). Around 521 million ha of forest land is
42 estimated to be legally owned, recognised, or designated for use by indigenous and local communities
43 as of 2017 (Rights and Resources Initiative 2018b), predominantly in Latin America, followed by
44 Asia. However in India approximately 40 million ha of forest land is managed under customary rights
45 not recognised by the government (Rights and Resources Initiative 2015b). In 2005 only 1% of land
46 in Africa was legally registered (Easterly 2008a).

47 Much of the world's carbon is stored in the biomass and soil on the territories of customary
48 landowners including indigenous peoples (Walker et al. 2014; Garnett et al. 2018), making securing

1 of these land tenure regimes vital in land and climate protection. These lands are estimated to hold at
2 least 293 GtC of carbon, of which around one-third (72 GtC) is located in areas where indigenous
3 peoples and local communities lack formal recognition of their tenure rights (Frechette et al. 2018).

4 Understanding the interactions between land tenure and climate change has to be based on underlying
5 understanding of land tenure and land policy and how they relate to sustainable development,
6 especially in low- and middle-income countries: such understandings have changed considerably over
7 the last three decades, and now show that informal or customary systems can provide secure tenure
8 (Toulmin and Quan 2000). For smallholder systems, (Bruce and Migot-Adholla 1994) among other
9 authors established that African customary tenure can provide the necessary security for long-term
10 investments in farm fertility such as tree-planting. For pastoral systems, (Behnke 1994; Lane and
11 Moorehead 1995) and other authors showed the rationality of communal tenure in situations of
12 environmental variability and herd mobility. However, where customary systems are unrecognised or
13 weakened by governments or the rights from them undocumented or unenforced, tenure insecurity
14 may result (Lane 1998; Toulmin and Quan 2000). There is strong empirical evidence of the links
15 between secure communal tenure and lower deforestation rates, particularly in intact forests
16 (Nepstad et al., 2006; Persha, Agrawal, & Chhatre, 2011; Vergara-Asenjo & Potvin, 2014). Securing
17 and recognising tenure for indigenous communities (such as through revisions to legal or policy
18 frameworks) has been shown to be highly cost effective in reducing deforestation and improving land
19 management in certain contexts, and is therefore also apt to help improve indigenous communities'
20 ability to adapt to climate changes (Suzuki 2012; Balooni et al. 2008; Ceddia et al. 2015; Pacheco et
21 al. 2012; Holland et al. 2017).

22 Rights to water for agriculture or livestock are linked to land tenure in complex ways still little
23 understood and neglected by policy-makers and planners (Cotula 2006a). Provision of water
24 infrastructure tends to increase land values, but irrigation schemes often entail reallocation of land
25 rights (Cotula 2006b) and new inequalities based on water availability such as the creation of a
26 category of tailenders in large-scale irrigation (Chambers 1988) and disruption of pastoral grazing
27 patterns through use of riverine land (Behnke and Kerven 2013).

28 Understanding of land tenure under climate change also has to take account of the growth in large-
29 scale land acquisitions (LSLAs), also referred to as land-grabbing, in developing countries. These
30 LSLAs are defined by acquisition of more than 200 ha per deal (Messerli et al. 2014a). Klaus
31 Deininger (2011) links the growth in demand for land to the 2007-2008 food price spike, and
32 demonstrates that high levels of demand for land at the country level are statistically associated with
33 weak recognition of land rights. Land grabs, where LSLAs occur despite local use of lands, are often
34 driven by direct collaboration of politicians, government officials and land agencies (Koechlin et al.
35 2016), involving corruption of governmental land agencies, failures to register community land claims
36 and illegal lands uses and lack of the rule of law and enforcement in resource extraction frontiers
37 (Borras Jr et al. 2011). Though data is poor, overall, small and medium scale domestic investment has
38 in fact been more important than foreign investment (Deininger 2011; Cotula et al. 2014). There are
39 variations in estimates of the scale of large-scale land acquisitions: the Nolte et al. (2016) report
40 concluded deals totalling 42.2 million ha worldwide. Cotula et al. (2014) using cross-checked data for
41 completed lease agreements in Ethiopia, Ghana and Tanzania conclude they cover 1.9%, 1.9% and
42 1.1% respectively of each country's total land suitable for agriculture. The literature expresses
43 different views on whether these acquisitions concern marginal lands or lands already in use thereby
44 displacing existing users (Messerli et al. 2014b). Land-grabbing is associated with and may be
45 motivated by the acquisition of rights to water, and erosion of those rights for other users such as
46 those downstream (Mehta et al. 2012). Quantification of the acquisition of water rights resulting from
47 LSLAs raises major issues of definition, data availability, and measurement. One estimate of the total
48 acquisition of gross irrigation water associated with land-grabbing across the 24 countries most
49 affected is 280 billion m³ (Rulli et al. 2013).

50 While some authors see LSLAs as investments that can contribute to more efficient food production at
51 larger scales (World Bank 2011; Deininger and Byerlee 2012), others have warned that local food
52 security may be threatened by them (Daniel 2011; Golay and Biglino 2013; Lavers 2012). Reports
53 suggest that recent land grabbing has affected 12 million people globally in terms of declines in

1 welfare (Adnan 2013; Davis et al. 2014). De Schutter (2011) argues that large-scale land acquisitions
2 will a) result in types of farming less liable to reduce poverty than smallholder systems, b) increase
3 local vulnerability to food price shocks by favouring export agriculture and c) accelerate the
4 development of a market for land with detrimental impacts on smallholders and those depending on
5 common property resources. Land grabbing can threaten not only agricultural lands of farmers, but
6 also protected ecosystems, like forests and wetlands (Hunsberger et al. 2017; Carter et al. 2017; Ehara
7 et al. 2018).

8 The primary mechanisms for combatting LSLAs have included restrictions on the size of land sales
9 (Fairbairn 2015); pressure on agribusiness companies to agree to the Voluntary Guidelines on the
10 Responsible Governance of Tenure of Land, Fisheries and Forests in the Context of National Food
11 Security, known as the VGGT, or similar principles (Collins 2014; Goetz 2013); attempts to repeal
12 biofuels standards (Palmer 2014); strengthening of existing land law and land registration systems
13 (Bebbington et al. 2018); use of community monitoring systems (Sheil et al. 2015); and direct protests
14 against the land acquisitions (Hall et al. 2015; Fameree 2016).

15 Table 7.7 sets out, in highly summarised form, some key findings on the multi-directional inter-
16 relations between land tenure and climate change, with particular reference to developing countries.
17 The rows represent different categories of landscape or resource systems. For each system the second
18 column summarises current understandings on land tenure and sustainable development, in many case
19 predating concerns over climate change. The third column summarises the most important
20 implications of land tenure systems, policy about land tenure, and the implementation of that policy,
21 for vulnerability and adaptation to climate change, and the fourth gives a similar summary for
22 mitigation of climate change. The fifth column summarises key findings on how climate change and
23 climate action (both adaptation and mitigation) will impact land tenure, and the final column, findings
24 on implications of climate change for evolving land policy.

25

1

Table 7.7 Major Findings on the Interactions between Land Tenure and Climate Change

Landscape or natural resource system	State of understanding of land tenure, land policy and sustainable development	Implications of land tenure for vulnerability and adaptation to climate change	Implications of land tenure for mitigation of climate change	Impacts of climate change and climate action on land tenure	Implications of climate change and climate action for land policy
Smallholder cropland	In South Asia and Latin America the poor suffer from limited access including insecure tenancies, though this has been partially alleviated by land reform. ¹ In Africa informal/customary systems may provide considerable land tenure security and enable long-term investment in land management, but are increasingly weakened by demographic pressures on available land resources increase. However, creation of freehold rights through conventional land titling is not a necessary condition for tenure security and may be cost-ineffective or counter-productive. ^{2,3,4,5} Alternative approaches utilising low cost technologies and participatory methods are available. ⁶ Secure and defensible land tenure, including modified customary tenure, has been positively correlated with food production increases. ^{7,8,9}	Insecure land rights are one factor deterring adaptation and accentuating vulnerability. ^{10,11} Specific dimensions of inequity in customary systems may act as constraints on adaptation in different contexts. ¹² LSLAs may be associated with monoculture and other unsustainable land use practices, have negative consequences for soil degradation ¹³ and disincentivise more sustainable forms of agriculture. ¹⁴	Secure land rights, including through customary systems, can incentivise farmers to adopt long-term climate-smart practices, ¹⁵ e.g., planting trees in mixed cropland/forest systems. ¹⁶	Increased frequency and intensity of extreme weather can lead to displacement and effective loss of land rights. ¹⁷ REDD+ programmes tend slightly to increase land tenure insecurity on agricultural forest frontier lands, - but not in forests. ¹⁸	Landscape governance and resource tenure reforms at farm and community levels can facilitate and incentivise planning for landscape management and enable the integration of adaptation and mitigation strategies. ¹¹
Rangelands	Communal management of rangelands in pastoral systems is a rational and internally sustainable response to climate variability and the need for mobility. Policies favouring individual or small group land-tenure may have negative impacts on both ecosystems and livelihoods. ^{19,20,21}	Many pastoralists in lands at risk from desertification do not have secure land tenure, and erosion of traditional communal rangeland tenure has been identified as a determinant of increasing vulnerability to drought and climate change and as a driver of dryland	Where pastoralists' traditional land use does not have legal recognition, or where pastoralists are unable to exclude others from land use, this presents significant challenges for carbon sequestration initiatives. ^{27,28}	Increasing conflict on rangelands is a possible result of climate change and environmental pressures, but depends on local institutions. ²⁹ Where land use rights for pastoralists are absent or unenforced, demonstrated potential for carbon sequestration may assist	Carbon sequestration initiatives on rangelands may require clarification and maintenance of land rights. ^{27,28}

		degradation. ^{22,23,24,25,26}		advocacy. ²⁸	
Forests	Poor management of state and open-access forests has been combatted in recent years by a move towards forest decentralisation and community co-management. ^{30,31,32,33,34,35} Land tenure systems have complex interactions with deforestation processes. Land tenure security is generally associated with less deforestation, regardless of whether the tenure form is private, customary or communal. ^{33,36,37,38} Historical injustices towards forest dwellers can be ameliorated with appropriate policy, e.g., 2006 Forest Rights Act in India. ³⁹	Land tenure security can lead to improved adaptation outcomes ^{40,41,42,43} but land tenure policy for forests that focuses narrowly on cultivation has limited ability to reduce ecological vulnerability or enhance adaptation. ³⁹ Secure rights to land and forest resources can facilitate efforts to stabilise shifting cultivation and promote more sustainable resource use if appropriate technical and market support are available. ⁴⁴	Land tenure insecurity has been identified as a key driver of deforestation and land degradation leading to loss of sinks and creating sources of GHGs ^{45,46,47,48,49} . While land tenure systems interact with land-based mitigation actions in complex ways, ³⁶ forest decentralisation and community co-management has shown considerable success in slowing forest loss and contributing to carbon mitigation. ^{30,31,32,33,34,35} Communal tenure systems may lower transaction costs for REDD+ schemes, though with risk of elite capture of payments. ¹⁶	Findings on both direction of change in tenure security and extent to which this has been influenced by REDD+ are very diverse. ^m The implications of land-based mitigation (e.g., BECCS) on land tenure systems is currently understudied, but evidence from biofuels expansion shows negative impacts on local livelihoods and loss of forest sinks where LSLAs override local land tenure. ^{50,51}	Forest tenure policies under climate change need to accommodate and enable evolving and shifting boundaries linked to changing forest livelihoods. ¹⁰ REDD+ programmes need to be integrated with national-level forest tenure reform. ¹⁸
Poor and informal urban settlements	Residents of poor and informal urban settlements enjoy varying degrees of tenure security from different forms of tenure. Security will be increased by building on de facto rights rather than through abrupt changes in tenure systems. ⁵²	Public land on the outskirts of urban areas can be used to adapt to increasing flood risks by protecting natural assets. ⁵³ Secure land titles in hazardous locations may make occupants reluctant to move and raise the costs of compensation and resettlement. ¹⁷	Urban land use strategies such as tree planting, establishing public parks, can save energy usage by moderating urban temperature and protect human settlement from natural disaster such as flooding or heatwaves. ⁵⁴	Without proper planning, climate hazards can undermine efforts to recognise and strengthen informal tenure rights without proper planning. ^{55,56}	Climate risks increase the requirements for land use planning and settlement that increases tenure security, with direct involvement of residents, improved use of public land, and innovative collaboration with private and traditional land owners. ^{56,57}
Riverscapes and riparian fringes	Well-defined but spatially flexible community tenure can support regulated and sustainable artisanal capture	Unequal land rights and absence of land management	Mitigation measures such as protection of riparian forests and grasslands can		Secured but spatially flexible tenure will enable climate change mitigation

	fisheries and biodiversity. ^{58,59,60,61,62,63,64}	arrangements in floodplains increases vulnerability and constrains adaptation. ⁶⁵ Marginalised or landless fisherfolk will be empowered by tenurial rights and associated identity to respond more effectively to ecological changes in riverscapes including riparian zones. ^{66,67,68,69}	potentially play a major role, provided rights to land and trees are sufficiently clear. ^{70,71}		in riverscapes to be synergised with local livelihoods and ecological security. ^{67,72}

11

12

1 In drylands, weak land tenure security, either for households disadvantaged within a customary tenure
2 system or more widely as such a system is eroded, can be associated with increased vulnerability and
3 decreased adaptive capacity (*limited evidence, high agreement*). There is *medium evidence* and
4 *medium agreement* that land titling and recognition programs, particularly those that authorise and
5 respect indigenous and communal tenure, can lead to improved management of forests, including for
6 carbon storage (Suzuki 2012; Balooni et al. 2008; Ceddia et al. 2015; Pacheco et al. 2012), primarily
7 by providing legally secure mechanisms for exclusion of others (Nelson et al. 2001; Blackman et al.
8 2017). However, these titling programs are highly context-dependent and there is also evidence that
9 titling can exclude community and common management, leading to more confusion over land rights,
10 not less, where poorly implemented (Broegaard et al. 2017). For all the systems, an important finding
11 is that land policies can provide both security and flexibility in the face of climate change, but through
12 a diversity of forms and approaches (recognition of customary tenure, community mapping,
13 redistribution, decentralisation, co-management, regulation of rental markets, strengthening the
14 negotiating position of the poor) rather than sole focus on freehold title (Quan & Dyer, 2008; K
15 Deininger & Feder, 2009; St. Martin, 2009) (*medium evidence, high agreement*). Land policy can be
16 climate-proofed and integrated with national policies such as NAPAs (Quan and Dyer 2008). Land
17 administration systems have a vital role in providing land tenure security, especially for the poor,
18 especially when linked to an expanded range of information relevant to mitigation and adaptation
19 (Quan and Dyer 2008; van der Molen and Mitchell 2016). Challenges to such a role include outdated
20 and overlapping national land and forest tenure laws, which often fail to recognise community
21 property rights and corruption in land administration (Monterosso et al. 2017), as well as lack of
22 political will and the costs of improving land administration programs (Deininger and Feder 2009).

23

24 **7.6.6. Institutional dimensions of adaptive governance**

25 Institutional systems that demonstrate the institutional dimensions, or indicators, in Table 7.8 enhance
26 the adaptive capacity of the socio-ecological system to a greater degree than institutional systems that
27 do not demonstrate these dimensions (*high confidence*) (Gupta et al. 2010; Mollenkamp and Kasten
28 2009). Governance processes and policy instruments supporting these characteristics are context
29 specific (*medium evidence, high agreement*) (Biermann 2007; Gunderson and Holling 2001; Hurlbert
30 and Gupta 2017; Bastos Lima et al. 2017a; Gupta et al. 2013a; Mollenkamp and Kasten 2009; Nelson
31 et al. 2010; Olsson et al. 2006; Ostrom 2011; Pahl-Wostl 2009; Verweij et al. 2006; Weick and
32 Sutcliffe 2001).

33 Consideration of these indicators is important when implementing climate change mitigation
34 instruments. For example, a ‘Variety,’ redundancy, or duplication of climate mitigation policy
35 instruments is an important consideration for meeting Paris Commitments. Given 58% of EU
36 emissions are outside of the EU Emissions Trading system, implementation of a ‘redundant’ carbon
37 tax may add co-benefits (Baranzini et al. 2017). Further, a carbon tax phased in over time through a
38 schedule of increases allows for ‘Learning.’ The tax revenues could be earmarked to finance
39 additional climate change mitigation and or redistributed to achieve the indicator of ‘Fair Governance
40 - Equity’. It is recommended that carbon pricing measures be implemented using information sharing
41 and communication devices to enable public acceptance, openness, provide measurement and
42 accountability (Baranzini et al. 2017; Siegmeier et al. 2018).

43 The impact of flood on a socio-ecological system is reduced with the governance indicator of both
44 leadership and resources (Emerson and Gerlak 2014). ‘Leadership’ pertains to a broad set of
45 stakeholders that facilitate adaptation (and might include scientists and leaders in NGOs) and those
46 that respond to flood in an open, inclusive, and fair manner identifying the most pressing issues and
47 actions needed. Resources are required to support this leadership and includes upfront financial
48 investment in human capital, technology, and infrastructure (Emerson and Gerlak 2014).

1 Policy instruments advancing the indicator of ‘Participation’ in community forest management
 2 include favourable loans, tax measures, and financial support to catalyse entrepreneurial leadership,
 3 and build in rewards for supportive and innovative elites to reduce elite capture and ensure more
 4 inclusive participation (Duguma et al. 2018) (see 7.6.4).

5 **Table 7.8 Institutional Dimensions or Indicators of Adaptive Governance**
 6 **This table represents a summation of characteristics, evaluative criteria, elements, indicators or**
 7 **institutional design principles that advance adaptive governance**

Indicators/Inst itutional Dimensions	Description	References
Variety	Room for a variety of problem frames reflecting different opinions and problem definitions	(Biermann 2007;
	Participation. Involving different actors at different levels, sectors, and dimensions	Gunderson and Holling 2001;
	Availability of a wide range or diversity of policy options to address a particular problem	
	Redundancy or duplication of measures, back-up systems	Hurlbert and Gupta 2017;
Learning	Trust	Bastos Lima et al. 2017a;
	Single loop learning or ability to improve routines based on past experience	Gupta, J., van der Grijp, N., Kuik 2013;
	Double loop learning or changed underlying assumptions of institutional patterns	
	Discussion of doubts (openness to uncertainties, monitoring and evaluation of policy experiences)	
Room for autonomous change	Institutional memory (monitoring and evaluation of policy experiences over time)	
	Continuous access to information (data institutional memory and early warning systems)	Mollenkamp and Kasten 2009;
	Acting according to plan (especially in relation to disasters)	Nelson et al. 2010;
Leadership	Capacity to improvise (in relation to self-organisation and fostering social capital)	Olsson et al. 2006;
	Visionary (Long term and reformist)	
	Entrepreneurial which leads by example	Ostrom 2011;
Resources	Collaborative	
	Authority resources or legitimate forms of power	Pahl-Wostl 2009;
	Human resources of expertise, knowledge and labour	
Fair governance	Financial resources	Verweij et al. 2006;
	Legitimacy or public support	
	Equity in relation to institutional fair rules	Weick and Sutcliffe 2001)
	Responsiveness to society	
	Accountability in relation to procedures	

8 **7.6.7. Inclusive Governance for Sustainable Development**

9 Many sustainable development efforts fail because of lack of attention to societal issues including
 10 inequality, discrimination, social exclusion and marginalisation (see Cross-Chapter Box 11: Gender in
 11 this chapter) (Arts 2017a). However, the human rights based approach of the 2030 Agenda and
 12 Sustainable Development Goals commits to leaving no one behind (Arts 2017b). Inclusive
 13 governance focuses attention in issues of equity and the human rights based approach for
 14 development as it includes social, ecological and relational components used for assessing access to,
 15 as well as the allocations of rights, responsibilities and risks with respect to social and ecological
 16 resources (medium agreement) (Gupta and Pouw 2017).

17 Governance processes that are inclusive of all people in decision making and management of land, are
 18 better able to make decisions addressing trade offs of sustainable development (Gupta et al. 2015) and
 19 achieve SDGs focusing on social and ecological inclusiveness (Gupta and Vegelin 2016). Citizen
 20 engagement is important in enhancing natural resource service delivery by citizen inclusion in
 21 management and governance decisions (see 7.5.5). In governing natural resources, focus is now not
 22 only on rights of citizens in relation to natural resources, but also on citizen obligations,
 23 responsibilities (Karar and Jacobs-Mata 2016; Chaney and Fevre 2001), feedback and learning
 24 processes (Tàbara et al. 2010). In this respect, citizen engagement is also an imperative particularly
 25 for analysing and addressing aggregated informal coping strategies of local residents in developing

1 countries, which are important drivers of natural resource depletions (but often overlooked in a
2 conventional policy development processes in natural resource management) (Ehara et al. 2018).

3 Inclusive adaptive governance makes important contributions to the management of risk. Inclusive
4 governance concerning risk integrates people's knowledge and values by involving them in decision
5 making processes where they are able to contribute their respective knowledge and values to make
6 effective, efficient, fair, and morally acceptable decisions (Renn and Schweizer 2009). Representation
7 in decision making would include major actors - government, economic sectors, the scientific
8 community and representatives of civil society (Renn and Schweizer 2009). Inclusive governance
9 focuses attention on the well being and meaningful participation in decision making of the poorest (in
10 income), vulnerable (in terms of age, gender, and location), and the most marginalised and is
11 inclusive of all knowledges (Gupta et al. 2015).

12

13 **7.7. Key uncertainties and knowledge gaps**

14 Uncertainties in land, society and climate change processes are outlined in 7.2 and Chapter 1. This
15 chapter has reviewed literature on risks arising from GHG Fluxes, climate change, land degradation,
16 desertification and food security, policy instruments responding to these risks, as well as decision
17 making and adaptive climate and land governance, in the face of uncertainty.

18 More research is required to understand the complex interconnections of land, climate, water, society,
19 ecosystem services and food, including:

- 20 • New models that allow incorporation of considerations of justice, inequality and human
21 agency in socio-environmental systems;
- 22 • Understanding how policy instruments and response options interact and augment or reduce
23 risks in relation to acute shocks and slow-onset climate events;
- 24 • Understanding how response options, policy, and instrument portfolios can reduce or augment
25 the cascading impacts of land, climate and food security and ecosystem service interactions
26 through different domains such as health, livelihoods, and infrastructure, especially in relation
27 to non-linear and tipping-point changes in natural and human systems.
- 28 • Consideration of trade-offs and synergies in climate, land, water, ecosystem services and food
29 policies;
- 30 • The impacts of increasing use of land due to climate mitigation measures such as BECCS,
31 carbon centric afforestation/REDD+ and their impacts on human conflict, livelihoods and
32 displacement;
- 33 • Understanding how different land tenure systems, both formal and informal, and the land
34 policies and administration systems that support them, can constrain or facilitate climate
35 adaptation and mitigation: and on how forms of climate action can enhance or undermine land
36 tenure security and land justice.
- 37 • Expanding understanding of barriers to implementation of land-based climate policies at all
38 levels from the local to the global, including methods for monitoring and documenting
39 corruption, misappropriation and elite capture in climate action;
- 40 • Identifying characteristics and attributes signalling impending socio-ecological tipping points
41 and collapse;
- 42 • Understanding the full cost of climate change in the context of disagreement on accounting
43 for climate change interactions and their impact on society, as well as issues of valuation, and
44 attribution uncertainties across generations;
- 45 • New models and Earth observation to understand complex interactions described in this
46 section.

- 1 • The impacts, monitoring, effectiveness, and appropriate selection of certification and
2 standards for sustainability (see 7.4.6.3) (ISEAL Alliance; Stattman et al. 2018) and the
3 effectiveness of its implementation through the landscape governance approach (Pacheco et
4 al. 2016) (see 7.6.3).

5 Actions to mitigate climate change are rarely evaluated in relation to impact on adaptation, SDGs, and
6 trade-offs with food security. For instance, there is a gap in knowledge in the optimal carbon pricing
7 or emission trading scheme together with monitoring, reporting and verification system for
8 agricultural emissions that will advance GHG reductions, food security, and sustainable land
9 management. Better understanding is needed of the triggers and leveraging actions that build
10 sustainable development and sustainable land management, as well as the effective organisation of the
11 science and society interaction jointly shaping policies in the future. What societal interaction in the
12 future will form inclusive and equitable governance processes and achieve inclusive just governance
13 institutions including. Land tenure?

14 As there is a significant gap in NDCs and achieving commitments to keep global warming well below
15 2°C (7.4.4.1), governments might consider evaluating national, regional, and local gaps in knowledge
16 surrounding response options, policy instruments portfolios, and sustainable land management
17 supporting the achievement of NDCs in the face of land and climate change.

18

19 **Frequently Asked Questions**

20 **FAQ 7.1 How can indigenous knowledge and local knowledge inform land-based** 21 **mitigation and adaptation options?**

22 Indigenous knowledge (IK) refers to the understandings, skills and philosophies developed by
23 societies with long histories of interaction with their natural surroundings. Local knowledge (LK)
24 refers to the understandings and skills developed by individuals and populations, specific to the place
25 where they live. These forms of knowledge are often highly context-specific and embedded in local
26 institutions, providing biological and ecosystem knowledge with landscape information. This means
27 they can contribute to effective land management, predictions of natural disasters and identification of
28 longer-term climate changes, for example, and IK can be particularly useful where formal data
29 collection on environmental conditions may be sparse. IK and LK are often dynamic, with knowledge
30 holders often experimenting with mixes of local and scientific approaches. Water management, soil
31 fertility practices, grazing systems, restoration and sustainable harvesting of forests, and ecosystem
32 based-adaptation are many of the land management practices often informed by IK and LK. LK can
33 also be used as an entry point for climate adaptation by balancing past experiences with new ways to
34 cope. To be effective, initiatives need to take into account the differences in power between the
35 holders of different types of knowledge. For example, including indigenous and/or local people in
36 programmes related to environmental conservation, formal education, land management planning and
37 security tenure rights is key to facilitate climate change adaptation. Formal education is necessary to
38 enhance adaptive capacity of IK and LK since some researchers have suggested these knowledge
39 systems may become less relevant in certain areas where the rate of environmental change is rapid
40 and the transmission of IK and LK between generations is becoming weaker.

41

42 **FAQ 7.2 What are the main barriers to and opportunities for land-based responses to** 43 **climate change?**

44 Land-based responses to climate change can be mitigation (e.g., renewable energy, vegetation or
45 crops for biofuels, afforestation) or adaptation (e.g., change in cropping pattern, less water intensive

1 crops in response to moisture stress), or adaptation with mitigation co-benefits (e.g., dietary shifts,
2 new uses for invasive tree-species, siting solar farms on highly degraded land). Productive land is an
3 increasingly scarce resource under climate change. In the absence of adequate deep mitigation in the
4 less land intensive energy sector, competition for land and water for mitigation and for other sectors
5 such as food security, ecosystem services and biodiversity conservation could become a source of
6 conflict and a barrier to land-based responses.

7 Barriers to land-based mitigation include opposition due to real and perceived trade-offs between land
8 for mitigation and food security and ecosystem services. These can arise due to absence of or
9 uncertain land and water rights. Significant upscaling of mitigation requires dedicated (normally
10 land-based) sources in addition to use of wastes and residues. This requires high land use intensity
11 compared to other mitigation options that in turn place greater demands on governance. A key
12 governance mechanism that has emerged in response to such concerns, especially during the past
13 decade are standards and certification systems that include food security and land and water rights in
14 addition to general criteria or indicators related to sustainable use of land and biomass with an
15 emphasis on participatory approaches. Other governance responses include linking land based
16 mitigation (e.g., forestry) to secure tenure and support for local livelihoods. A barrier to land-based
17 mitigation is our choice of development pathway. Our window of opportunity/ whether or not we face
18 barriers or opportunities to land based mitigation depends on socio-economic decisions or
19 pathways. If we have high population growth and resource intensive consumption (i.e., SSP3) we will
20 have more barriers. High population and low land use regulation results in less available space for
21 land based mitigation. But if we have the opposite trends (SSP1) we can have more opportunities.

22 Other barriers can arise when in the short term adaptation to a climate stress (eg increased dependence
23 on ground-water during droughts) can become unsustainable in the longer term and become a
24 maladaptation. Policies and approaches that lead to land management that synergises multiple
25 ecosystem services and reduce trade-offs could find greater acceptance and enjoy more success.

26 Opportunities to obtain benefits or synergies from land-based mitigation and adaptation arise
27 especially from their relation to the land availability and the demand for such measures in rural areas
28 that may otherwise lack incentives for investment in infrastructure, livelihoods and institutional
29 capacity. After decades of urbanisation around the world facilitated by significant investment in urban
30 infrastructure and centralised energy and agricultural systems, rural areas have been somewhat
31 neglected even as farmers in these areas provide critical food and materials needed for urban areas. As
32 land and biomass becomes more valuable, there will be benefits for farmers, forest owners and
33 associated service providers as they diversify away from feed and feed into economic activities
34 supporting bioenergy, value-added products, preservation of biodiversity and carbon sequestration
35 (storage).

36 A related opportunity for benefits is the potentially positive transformation in rural and peri-urban
37 landscapes that could be facilitated by investments that prioritise more effective management of
38 ecosystem services and conservation of water, energy, nutrients and other resources that have been
39 priced too low in relation to their environmental or ecological value. Multifunctional landscapes
40 supplying food, feed, fiber and fuel to both local and urban communities in combination with reduced
41 waste and healthier diets could restore the role of rural producers as stewards of resources rather than
42 providing food at the lowest possible price. Some of these landscape transformations will function as
43 both mitigation and adaptation responses by increasing resilience even as they provide value-added
44 bio-based products.

45 Governments can introduce a variety of regulations and economic instruments (taxes, incentives) to
46 encourage citizens, communities and societies to adopt sustainable land management practices with
47 further benefits in addition to mitigation. Windows of opportunity for redesigning and
48 implementing mitigation and adaptation can arise in the aftermath of a major disaster or extreme

1 climate event. They can also arise when collective action and citizen science motivate voluntary
2 shifts in lifestyles supported by supportive top-down policies.

1 Supplementary Material

3 Supplementary information to Section 7.2

5 The burning embers diagrams (Figure 7.1, 7.2 and 7.3) outline risks associated with climate
6 change as a function of global warming, socio-economic development and mitigation choices.
7 Diagrams indicate transitions between undetectable, moderate, high, and very high risks to
8 humans and ecosystems. The method is based on a literature review of estimated impacts at
9 different global mean surface temperature levels (O’Neill et al. 2017) on different components of
10 desertification, land degradation and food security, including emerging literature on Shared
11 Socio-economic Pathways (SSPs) as well as literature from IPCC AR5 and SR15.

13 Most studies focus on changes in hazards as a function of climate change (e.g. as represented by
14 RCP scenarios or other climate change scenarios) or climate change superimposed on present-day
15 exposure. Only a limited number of studies focus on changes in risk as a function of both RCPs
16 and SSPs (climate and socio-economic change and adaptation decisions). This was addressed by
17 splitting the embers into different figures. Figure 7.1 focuses on the impact of climate change on
18 risk, under present-day exposure and vulnerability. Figure 7.2 examines the relationship between
19 climate change and risks under two SSPs (SSP1 and SSP3). Figure 7.3 depicts risks to humans
20 and ecosystems as a function of the land area employed for mitigation through bioenergy
21 plantations.

23 Further, a formal expert elicitation protocol, based on the modified-Delphi technique (Mukherjee
24 et al. 2015) and the Sheffield Elicitation Framework (Oakley and O’Hagan 2016; Gosling 2018),
25 was followed to develop threshold judgments on risk transitions. Specifically, experts participated
26 in a multi-round elicitation process, with feedback of group opinion provided after each round:
27 the first two rounds involved independent anonymous threshold judgment, and the final round
28 involved a group consensus discussion (von der Gracht 2012). To strengthen the rigor of
29 developing expert consensus on risk transitions (Hasson and Keeney 2011), the protocol pre-
30 specified the following prior to beginning the elicitation exercise (Grant et al. 2018): the research
31 question, eligibility criteria and strategy to recruit experts, research materials, data collection
32 procedure, and analysis plan. This systematic process of developing expert consensus on
33 threshold judgments for risk transitions can better inform subsequent analytical approaches—an
34 approach that may be further developed for use in future IPCC cycles (Bojke et al. 2010; Sperber
35 et al. 2013). References for the current and past assessments are listed at the end of this document
36 and by the relevant tables.

38 **Table SM7.1: literature considered in the expert judgement of risk transitions for figure 7.1**

Reference	Risk	variable (unit)	Direction of impact	climate scenario	Time frame	D/A of current impact	Impact at 1 degree	Impact at 2 degree	Impact at 3 degree	Impact at 4 degree	Impact at 4.5 degree	Adaptation potential	Region (Including Regional Differences)

7. SM. 1. Additional embers

4

5 Details of two embers (nutrition and coastal degradation) where not included in Chapter 7 due to
6 space limitations. Changes in atmospheric CO₂, will result in reduced nutritional value of crops
7 (iron, protein, zinc, other micronutrients, and increases in mycotoxins), impacting food
8 utilization, with potential risks to health of vulnerable groups such as children and pregnant
9 women (*high confidence, high agreement*). This may create nutrition-related health risks for 600
10 million people (Zhou et al. 2018). Further details are provided in Chapter 5 of this Report.

11

12 Coastal flooding and degradation bring risk of damage to infrastructure and livelihoods. There are
13 very few global studies investigating past changes in coastal degradation (erosion and flooding)
14 and associated risk (Muis et al. 2018; Mentaschi et al. 2018), yet strong evidence exists that

1 anthropogenic climate change is already affecting the main drivers of coastal degradation,
 2 including: mean and extreme sea level (IPCC, 2013), storm surges (Wahl et al. 2015) and tropical
 3 cyclones (Kossin 2018). It is also clear that land-based processes, such as groundwater extraction
 4 and land subsidence, may impact coastal degradation {See Chapter 4, including 4.8.5}.

5
 6 At 1.5°C there is a high risk of destruction of coastal infrastructure and livelihoods (Hoegh-
 7 Guldberg et al. 2018) (*high confidence*). There is an associated strong increase in people and
 8 assets exposed to mean and extreme sea level rise and to coastal flooding above 1.5°C. Very high
 9 risks start to occur above 1.8 °C (*high confidence*) (Hanson et al. 2011; Vousdoukas et al. 2017;
 10 Jevrejeva et al. 2018; Hallegatte et al. 2013). Impacts of climate change on coasts is further
 11 explored in the IPCC Special Report on the Ocean and Cryosphere in a Changing Climate.
